chamber, the air will also be exhausted through the apertures on the lids of the tins. Hence the contents of the tins will, for the time being, be in a vacuum. In this condition the aperture of each tin is soldered over by means of an electric soldering bolt, which can be moved from the outside of the chamber in the vacuum, within a sufficiently large field to enable a certain amount of freedom of action inside the chamber. The operations inside the chamber are seen through a small observation window, and an electric light enables the soldering bolt to be accurately handled. Soldering having been accomplished in one tin is successfully carried out on the others, the moving platform in the circular vacuum chamber being actuated from the outside, so as to bring each tin under the field of the soldering bolt. As soon as the apertures have been soldered, a valve is opened, and air is allowed to enter the circular vacuum chamber, and it will be observed that the tops and bottoms of the tins immediately yield to the atmospheric pressure, being pressed inwards. Any tins which do not yield in this manner are faulty and have been badly soldered. The defect should be remedied, the aperture in the cover repunctured, and the tins should be treated again. The tins can now be removed from the vacuum chamber, and are ready for the next operation.

The tins are now placed in a cage belonging to a vertical autoclave, and closely packed together. The number of autoclaves used would be in direct proportion to the business to be done. The cage of the autoclave is carried by means of tackle suspended from an overhead rail. It is raised sufficiently high to clear the top of the autoclave, and is then lowered into it, the tins being submerged in a bath of hot water. The autoclave has a steam jacket, which maintains the temperature of the water inside, but when the cage has been lowered the cover of the autoclave is screwed down, and by means of steam pressure the temperature inside is elevated to 240 F., at which degree it is maintained until the hams are cooked, the length of time required varying slightly, according to weight. A large ham will take about four hours to cook, smaller ones being in proportion; the average time required being 3¾ hours. This operation of cooking the fresh hams in the tins prevents any loss of weight, and also maintains all the flavour of the meat; the advantages over the old-fashioned way are apparent. The advantage of cooking the tins *in water* inside the autoclaves lies in the equalisation of the pressure which results. In so far as the keeping properties are concerned, it may be safely stated that the hams are never likely to deteriorate, or alter in any way within the limits of several years after being tinned in the manner indicated.

Hitherto only the tinning of hams by the vacuum method has been spoken of, but the same method can be applied to corned beef, potted beef, brawn, sausages, galantines, and every other form of preserved meats. Army rations, such as sliced bacon, bacon and vegetables, or meat with vegetables, can be expeditiously and effectively canned by this method, which may be described as being applicable to the preservation of every kind of perishable food in tins. The adjustment of the vacuum chamber to packages of different sizes is a matter of detail.

ENGINEERING NOTES.

The Mont d'Or Tunnel.—To the list of notable railway tunnels in operation a new name has been added—the Mont d'Or. Robbed by the war of the publicity which so important an event would receive in normal times, the international railway link between France and Italy, *via* Switzerland—15 miles long, including the 3¾ mile tunnel—was recently opened to traffic without ceremony. To the layman the news means the shortening of the route from Frasne to Vallorbe by 11 miles, eliminating the distance to Pontarlier by the old line; but to the engineer the event marks the termination of a five years' struggle against unusual difficulties. From Frasne the double-track line extends, in the open, across a marsh where thousands upon thousands of cubic yards of material were swallowed by the ooze before a stable embankment was secured. But the trouble did not stop here, for in the tunnel excessive inflows of water were encountered, causing the collapse of sections of the roof, and threatening to stop the work. Finally an aqueduct had to be built within the bore to carry off the water. In spite of these handicaps the work was continued, and its completion is a tribute to the courage and endurance of the men who have made it. The improvements carried out over this section, and on the track generally, mean a gain of from forty-five minutes to one hour on the duration of the journey between Paris and Lausanne. The large radii of the curves are favourable for speed, and in winter the tunnels and pine forests through which the line passes are a protection against snowstorms. The motive power through the bore is steam, but the ventilation is said to be so perfect that the locomotive gases cause practically no inconvenience.

Cement-protected Steel Construction.—*The Engineer* reports that in connection with the enlargement of the Victoria terminus of the London, Brighton and South Coast Railway, a covering of nearly pure concrete to all the overbridges in the station has been adopted. The ironwork is thus protected from corrosion from the weather, and from the steam emitted by the locomotives in passing under it. At the Cortland Street ferry end of the Pennsylvania and New York City Railway the whole of the steelwork has been covered with a thin coating of sand and cement, sprayed on it by means of a "cement gun," after carefully cleaning the surfaces of the steelwork. A test-piece successfully resisted the most severe trials. It was kept in moist salt air for three days, in salt water for three days, in a temperature of [illegible] degrees

below zero for forty-eight hours, and then allowed to thaw in a warm room; then it was placed on a boiler subjected to a heat of 110 degrees for three days; then it was dropped 2 feet on a wooden floor, again on a concrete one, and showed no signs of cracking.

Turbine-electric Propulsion for Battleships.—In the *Journal of the Society of American Engineers*, Lieut.-Commander P. W. Foote, U.S.N., reviews the status of battleship propulsion by reciprocating engines, direct-connected, geared and electric-turbo units, and concludes that while turbine-electric drive has yet to be tested in a battleship installation, it promises to be superior to every competitor to an extent that will represent a distinct epoch in the engineering military efficiency of the Navy. The acceptance of the collier "Jupiter" by the Government, after tests in which this pioneer turbo-electric vessel surpassed the requirements, pointed the way to even more suitable applications of this type of equipment. The discrepancy between the economical speeds of turbines and of propellers has been so great in the past, that reduction through mechanical gearing or by the electric motor has become wellnigh absolutely essential to the kind of service demanded in the modern navy. Facility of control, economical operation at moderate speeds employed in cruising, and efficient use of power at high speed through heavy seas, are points of immense importance to battleship or cruiser. These appear to be capable of greater realisation with electric drive than with any other method of propulsion. Simplicity, the use of well-tried equipment, and service reliability, demonstrated by over a year's operation on the "Jupiter," are on its side. In manœuvring and backing the flexibility of electrical operation is of great value, and the single advantage of being able to maintain top speed in any sea with the electric drive, with no racing of propellers, might alone become the deciding factor in a naval campaign. The double "squirrel cage" induction motor exactly fulfils the requirement for ship propulsion where wide variation of loads, speeds, and operating conditions is found. Since the speeds of motors and turbo-generators depend upon the inverse relation between their poles, a reduction from the efficient turbine range of 1,200 3,600 to the efficient propeller range of 100 125 revolutions per minute is readily obtained. Electric propulsion, however, does not lend itself so well to ships of small horse-power, because the size of the motors mechanically limits the number of poles, and the speed reduction is much more limited than in ships where large motors can be used. About 5,000 shaft horse-power is roughly the present minimum for electric propulsion, mechanical reduction gearing being generally more efficient and desirable below this power unless facility of control is paramount. The electric drive permits great facility of control either from the bridge, conning tower, or any fire-control station, and in this point far exceeds the reciprocating engine, direct-connected or geared turbine. The propeller may be started, stopped, or run astern by a simple hand movement remote from the turbine room, and, similarly, turbine speeds may be electrically governed from a distance. The type of induction motor mentioned above has as high backing power as the propeller design permits, and in this way equals the reciprocating engine, and far excels the turbine mechanical-reduction gear. Throughout the electrical installation the equipment is generally operating near its rated load, which spells economy with capitals. Considering all the military and economical characteristics desired in a battleship, turbine direct-connected ships are not the equal of reciprocating-engine vessels, even when the former are fitted with cruising turbines having mechanical-reduction gears. Reduced complication, decreased weight of machinery and boilers, economy of space, and low maintenance requirements, are also closely identified with the turbo-electric drive; the danger of trouble in circuits is nominal, and the subdivision of the turbine room into water-tight compartments is greatly facilitated with the electrical installation. Constant-speed vessels have less to gain in the use of electric drive, but warships of high power are certain to find it of great value unless difficulties which are not apparent develop in service. The United States Navy Department has decided to provide turbo-electric propulsion equipment for the 32,000-ton super-Dreadnought "California," the largest battleship ever planned for that country's service, and the record of this vessel will be watched with interest by engineers and seamen the world over.

Large Submarine Engines. Both of the leading Italian Diesel-engine manufacturing firms the Fiat Company, of Turin, and Franco Tosi, of Legnano —the *Times* says, are constructing motors of the heavy oil type for installation in submarines, with a power of 1,300 B.H.P. Both designs are of the two-cycle type, and the motors built by the Fiat company, of which two have already been constructed and tested, are especially interesting. They are six-cylinder machines, with a speed of about 350 to 400 revolutions per minute, and are arranged with scavenging pumps below the working cylinders, this being a design that has been adopted by the firm for several years past. The air-compressor for the injection and starting air is driven off the end of the crank-shaft. The engine is directly reversible, the operation of reversing being facilitated by the fact that in each cylinder cover there are only two valves, the fuel-inlet valve and starting-air valve. The scavenging air is admitted through ports in the bottom of the cylinder, so that no scavenging valves of the ordinary type are necessary.

Many Inventions.—At a recent meeting presided over by Admiral Lord Charles Beresford, on the motion of Admiral Sir E. R. Fremantle, the project of a National Inventions Development Association was approved and recommended to public

support. According to the *Manchester Guardian*, it has been stated semi-officially that the authorities are not likely to be able to find time to "investigate more than a small proportion of the undeveloped inventions submitted." It is proposed, therefore, that the societies and institutes representing scientific professions should nominate representatives to serve on the Association's general committee and to appoint expert consultants and advisers in their respective branches. In the first place, all inventions, etc., will be considered by a small staff of men sufficiently qualified to sift the promising from the impracticable. Inventions of merit will be promptly referred to the expert consultants. Inventions will be patented where this is necessary, the inventor's rights being fully safeguarded. Practical tests will then be made, and if these are satisfactory the Government will be approached. It is proposed to provide rewards for notable improvements in submarines, aircraft, aerial weapons, trenching and sapping appliances, etc.

Manufacture of Cement in Queensland. In a recent number of these Notes we spoke of Greater Britain beginning to manufacture from some of her own raw material. Now we hear that Queensland has started the manufacture of cement. Owing to the shortage of German and Belgian supplies, a good deal of attention is being given to the manufacture of this material abroad, and in other places where limestone, shale, or clay and coal can be obtained of suitable quality, and in sufficient quantities to make the manufacture likely to be successful and remunerative. The Queensland Cement and Lime Company has now arranged to establish a works at Darra, near Brisbane. The plant is designed to produce about 10,000 tons of cement per annum. The complete contract for the supply and erection of the plant, which will be of entirely British manufacture, has been placed with Messrs. Noyes Brothers, Sydney. Grinding mills of the combination ball and tube mill type, and a kiln 140 feet long and 8 feet in diameter, will be erected; and these, together with all the subsidiary plant, will be electrically driven, direct-coupled wherever possible. The motors are for three-phase fifty cycles, 440 volts, and will be supplied with power from generating plant in the works, which will be direct-coupled to vertical high-speed engines. The general lay-out of the plant has been made with the expectation that the works will soon be duplicated and even further increased.

NOTES ON BOOKS.

MODERN ILLUMINANTS AND ILLUMINATING ENGINEERING. By Leon Gaster and J. S. Dow. London: Whittaker & Co. 1915. Price 12*s*. 6*d*.

The material from which this valuable volume is compiled has, for the most part, appeared in *The Illuminating Engineer*, the organ of the Illuminating Engineering Society and of the two authors Mr. Gaster is the founder and honorary secretary of that Society, and Mr. Dow is the editor of its journal. The book, however, is in no sense a reprint of previously published matter. Not only does it contain a large amount of new material, but the articles on which it is founded have been recast and rearranged into an orderly and valuable account of the present condition of artificial lighting.

It commences with a brief historical summary, which, perhaps, those interested in the history of invention would have preferred to have had a little elaborated; but, of course, it is the scientific and not the historical aspect of the subject with which Messrs. Gaster and Dow have been concerned.

The three principal forms of illumination dealt with are, of course, gas lighting, electric lighting, and lighting by oil, oil-gas, and acetylene. Each of these subjects has a chapter to itself.

The chapter on "Illumination and the Eye" is important and interesting. From this it appears that the supposed effects of the ultra-violet rays upon the human eye, to which attention was first drawn in this country by Mr. Gaster in a paper read before the Society in February, 1913, do not appear to be as important as was originally thought.

The chapter on the "Measurement of Light and Illumination" contains a great deal of novel information—novel at least to those who have not followed the subject in the pages of *The Illuminating Engineer*. The various methods employed, and the apparatus used both in outdoor and interior illumination, are very fully dealt with, and naturally enough the considerations involved apply almost equally well whatever method of illumination may be employed.

A useful, and apparently fairly complete, list of works dealing with illumination and photometry is given in an appendix.

PRACTICAL GILDING, BRONZING, LACQUERING, AND GLASS EMBOSSING. By Frederick Scott-Mitchell. London: The Trades' Papers Publishing Co. Ltd. 3s.

In 1905 Mr. F. Scott Mitchell published a book on "Practical Gilding, Bronzing, and Lacquering," which received many appreciative notices from the technical press, and was generally welcomed as a very useful manual by practical workers. The present volume is in some sense a second edition of the earlier book, but it has been revised with great care, and additional chapters have been written on Glass Embossing, Gesso and Relief Decoration, Mosaic Work, and Leading Points, while the scales of charges for all kinds of work have been brought up to date. The text gives a very clear and concise account of the various tools and processes described; the fresh illustrations which have been added to the second edition are useful and instructive; and the whole book forms a welcome addition to "The Decorator Series of Practical Handbooks."

GENERAL NOTES.

INVENTIONS BOARD.—The Secretary of the Admiralty makes the following statement:—It was announced on July 5th that Admiral of the Fleet Lord Fisher of Kilverstone had been appointed Chairman of the Inventions Board, established to assist the Admiralty in co-ordinating and encouraging scientific effort in relation to the requirements of the Naval Service. The arrangements for the organisation of the Board have now been completed. It will comprise: (*a*) a Central Committee; (*b*) a Panel of Consultants composed of scientific experts, who will advise the main committee on questions referred to them. The Central Committee will consist of: Lord Fisher of Kilverstone, G.C.B., O.M. (President); Sir J. J. Thomson, O.M., F.R.S.; Hon. Sir C. A. Parsons, K.C.B., F.R.S.; G. T. Beilby, Esq., F.R.S. The Consulting Panel will comprise the following list, which will be added to from time to time as necessary: Professor H. B. Baker, F.R.S.; Professor W. G. Bragg, F.R.S.; Professor H. C. H. Carpenter; Sir William Crookes, O.M., F.R.S.; W. Duddell, Esq., F.R.S.; Professor Percy Frankland, F.R.S., Professor Bertram Hopkinson, F.R.S.; Sir Oliver Lodge, F.R.S.; Professor W. J. Pope, F.R.S.; Sir Ernest Rutherford, F.R.S.; G. Gerald Stoney, Esq., F.R.S.; Professor the Hon. R. J. Strutt, F.R.S. The Board is accommodated temporarily in the Whitehall Rooms, Hôtel Métropole, Whitehall Place, S.W., but at an early date (which will be announced in due course) it will be transferred to permanent offices at Victory House, Cockspur Street, S.W. Communications should be addressed to the Secretary, Board of Invention and Research.

ARMY BISCUITS.—An exhibit, brought up to date, illustrating the work done in connection with an investigation undertaken to determine the origin of damage to Army biscuit by insect pests, has just been installed in the Central Hall of the Natural History Museum. Examples are shown of the old kind of Army biscuit infested by moth, etc., and condemned by the military authorities as unfit for food, and of the new biscuit now being served out to the troops. The researches, which have been carried out jointly by the War Office and the British Museum (Natural History), have ensured the protection of Army biscuit from the possibility of such attacks by insects in the future.

ECONOMY IN FOOD.—In a circular just issued to local education authorities, the Board of Education direct attention to the urgent importance of economy in food, and in particular to the desirability of restricting the consumption of meat. They point out that much can be done to educate the public as to the respective cost and nutritive value of other foodstuffs by informal instruction, adapted to the needs of housewives and others, and that lectures and demonstrations can readily be organised in connection with schools for mothers, maternity centres, mothers' meetings, and otherwise. It is hoped that, in view of the issues involved, a beginning may be made with such work even during the present summer months. Accordingly the Board have decided to make special grants in aid of instruction for housewives in economical cookery, including the following topics: (*a*) The principal kinds of nourishing foods which may be employed to supplement the use of meat and fish; (*b*) the kinds of food specially suitable for children; (*c*) the employment of economical methods in the purchase, preparation, and cooking of meat, fish, and other nourishing foods; (*d*) the use of simple cooking equipment, apparatus, and utensils, with special regard to economy in the use of fuel.

INDIAN TRADE IN 1914.—The returns of the total imports and exports of merchandise into and from India in 1914, compiled by the Department of Statistics, show that, in spite of the war having been going on for five out of the twelve months, the total imports into India were actually larger than in 1912, and only 14 per cent. less than in 1913. Exports were only slightly more affected. They are valued at £138,000,000 sterling in 1914, against £160,000,000 in 1913 and £150,000,000 in 1912. Trade with Europe was chiefly affected, that with America, Australia, and the Far East showing comparatively little variation. The main fact which appears to emerge is that the first seven months of the year were such bumper ones as almost to make up for the depression of the remaining five months.

JAPANESE NAVAL SHIPYARDS, 1914.—The most interesting vessel built in Japan in 1914 was the battleship "Fuso," of 30,600 tons displacement. This ship was launched at Kure in March, 1914, she is one of the largest and most powerful battleships afloat, carries twelve 14-in. guns in six turrets, all arranged on the centre line of the ship. It is expected that the ship will be put into commission during the latter part of this year. There are under construction three sister ships—the "Yamashiro" at Yokohama, the "Hinga" at Nagasaki, and the "Ise" at Kobe. The propelling machinery of these ships consists of Brown-Curtis turbines and Japanese Admiralty type water-tube boilers, with the exception of the "Hinga," which is fitted with Parsons turbines. The battleship "Hiyei" was completed last summer, and has been engaged in actual service; her two sister ships, the "Kirishima" and "Haruna," are undergoing speed trials. After the outbreak of the present war, a supplementary budget was passed, authorising the construction of ten destroyers of 600 tons displacement and 9,500 i.h.p. These were to be completed in six months. The hulls, machinery, and equipment of the vessels are to be constructed entirely in Japan.

Journal of the Royal Society of Arts.

No. 3,271. VOL. LXIII.

FRIDAY, JULY 30, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

COUNCIL.

At their last meeting the Council elected Sir JOHN WOLFE-BARRY, K.C.B., LL.D., F.R.S., a Vice-President of the Society, to fill the vacancy caused by the resignation of the Duke of Bedford, K.G.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Monday afternoon, the 26th inst. Present:—

Sir Steyning William Edgerley, K.C.V.O., C.I.E. (Chairman of the Committee), Sir Arundel T. Arundel, K.C.S.I., Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Sir M. M. Bhownaggree, K.C.I.E., William Coldstream, B.A., I.C.S. (retired), Sir (Frederick) William Duke, K.C.S.I., K.C.I.E., Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Sir John Jardine, K.C.I.E., M.P., Sir Frederic S. P. Lely, K.C.I.E., C.S.I., Sir Patrick Playfair, C.I.E., Sir James Wilson, K.C.S.I., with S. Digby, C.I.E. (Secretary of the Section).

SPECIAL WAR LECTURE ON "FIELD TELEPHONES."

On Wednesday afternoon, July 28th, Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics at the City and Guilds Technical College, Finsbury, delivered a Special War Lecture on "Field Telephones."

On the motion of the Chairman, the Hon. RICHARD CLERE PARSONS, a vote of thanks was accorded to Mr. Darling for his interesting lecture.

The lecture will be published in an early issue of the *Journal*.

A SHORT HOLIDAY IN BELGIUM.

By T. B. GRIERSON, M.Inst.C.E.

In the summer of 1914 the writer spent a pleasant holiday in visiting some of the beautiful old-world cities of Belgium. This was about six weeks before the Germans began their unjustifiable attack on that country. There was at that time apparently no idea of war, nor any likelihood of it, so far as the man in the street could see.

With the intention of having a fairly long sea passage, the writer decided to travel by the Lancashire and Yorkshire Railway Company's steamers which run between Goole and Ghent *via* the Terneuzen-Ghent Ship Canal. Leaving London (King's Cross) on June 10th, 1914, he arrived *via* Doncaster at Goole.

The Goole docks, which are extensive, have recently been improved since their occupation by the Lancashire and Yorkshire Railway Company. New sheds, with up-to-date electric cranes and facilities for loading and unloading ships, have resulted in a great increase of valuable traffic, both inwards and outwards, to the railway company. This company may truly be said to be one of the best-managed and most enterprising of our English railways.

Having got safely out of the wonderful complication of inner docks and locks, barges and steam and sailing vessels going in and coming out, we found ourselves at last in the tidal sea-locks, and thence in the River Ouse. The river is so wide at this point that it looks like an arm of the sea; it is also so comparatively shallow that ships going up or down it, especially at low tide, must be carefully piloted for several miles. It is remarkable that this fine tidal river has never been made to deepen itself automatically by the construction of training walls. The [illegible] from York, reinforced by the waters of the Trent and both discharging into the Humber above the city of Hull, aided by the tidal waters, would rapidly deepen the channel. This would enable ships to go up and down at low water instead of being obliged to wait for the rise of tide, as at present.

Steaming down the river, we generally "hugged" the banks—now on one side, then on the other. Sometimes we were in mid-stream, according to the vagaries of the natural bed which the river had cut out for itself. On the left bank, on our port side, we saw the city of Hull, evidently in a state of great excitement preparing for the formal opening of the new dock by the King. This magnificent dock was opened on June 22nd, 1914, and the city was given a Lord Mayoralty by His Majesty.

Lower down on the opposite bank of the river lies Immingham, with its immense area of new docks, about which so much has been heard as to its equipment and facilities for dealing with overseas traffic *via* the Great Central Railway. If rumour is to be believed, hopes are entertained by the owners that the Admiralty may purchase these docks for use as oil-fuel stores to replace their smaller depot close by.

Looking at Immingham docks from the sea front, with their great wharves, jetties, powerful cranes and warehouses, one would think they ought to make a splendid base for the Navy, in view of the Government's recent investment in oil-fields and the Admiralty decision to use oil fuel very largely in our warships.

The weather being clear, Grimsby and Cleethorpes could be seen on our right, or starboard, side and Spurn Head on our left. Spurn Head was the last piece of England to be seen on our journey to Holland and Belgium. We then steamed on at a speed of about eleven knots an hour, until we arrived at the old Dutch town of West-Kapelle, whose church tower is used as a lighthouse. Here, owing to a dense fog, we were obliged to anchor for some hours; here also the Government pilot came on board to take us along the Dutch coast to Flushing.

Although the weather was fine and warm and the sun shining over our heads, there was nothing to be seen inside our small ring of fog-encircled bluish-green water except jellyfish and the many porpoises which looked soft and curved, happy and handsome, as they tumbled about in the sea. When the fog lifted we saw a large number of steamers which had also been at anchor. Many of these vessels were making for the same general destination as ourselves, namely, the River Scheldt.

As we passed along the coast of Walcheren (Holland) we could see the great number of groins running out into the sea for the protection of the land. The coast of Holland lies very low, although many of its sand dunes, our pilot told us, rise to a height of thirty metres, or nearly a hundred feet. The entire coast is protected by groins, some of which are of concrete but most are of timber. These groins are cleverly arranged as to height and angle with the coast, so as to get the greatest protection at the least cost. Dutch engineers are great experts in land reclamation and coast protection. Those who have had much experience of that class of engineering can appreciate their work.

The rampart walls and fortifications for the protection of the coast towns are generally of concrete with a facing of brickwork towards the sea. The groins, however, are the main protection of the land which has been so hardly won from the sea. They prevent it from "reverting to type" and going back to become sand again in the bosom of its enemy.

The towns along the Dutch coast are very picturesque. The windmills and the quaint old cottages with their bright red tiles give a warm and homelike appearance. The contrast between the Yorkshire coast at Goole, with its woods and fine trees, and the coast of Holland, which is practically bare, is very marked.

Arrived off the town of Flushing, we could see the old brickfaced fortifications, standing very high above the sea-level, their bases and foundations protected with groins on the beach. Flushing was once a strongly-fortified town but is now a pleasure and bathing resort. We could see the Grand Hotel, a fine building with a tower at each end. There were also many "pensions" and a large number of bathing-boxes along the coast, the splendid sands being crowded with bathers. It looked incongruous to see in places so ancient and old fashioned great up-to-date electric travelling cranes and gantries, denoting large engineering works and shipbuilding yards.

We dropped our first pilot and took up a second here, to conduct us through the intricacies of the West Scheldt to Terneuzen.

The deep-water channels off the coast of Holland and in the estuary of the Scheldt are carefully defined by the most recent types of beacon-buoys. Some are of the bell-buoy type; others are whistle buoys. The latter are filled with compressed air, and when the buoy is rocked by the waves in rough weather the air is automatically allowed to escape against a sharp edge, thus causing a whistling sound which can be heard at great distances. There are also "lightships" anchored over or close to various shallow spots. These ships are of the usual type, with three masts. They act as beacons by day and, when the great lanterns are lit and hoisted up to the masthead, as danger signals at night. These precautions are very necessary for the protection of the immense number of steam and sailing ships which pass to and fro between Great Britain and the Continent.

A not unusual sight was that of a steam tug with two or three large barges in tow carrying coal and general merchandise between England and Belgium. Some of these barges towed between England and Ghent carry as much as 3,000 tons of actual cargo.

In consequence of the inferior quality of the coal found in Holland and Belgium, English coal, coke and slack are in great demand and form a large proportion of the exports from this country. There is also an immense traffic in general merchandise. For instance, the steamship "Wharfe," in which the writer travelled, had coal in her lowest hold, and carried, amongst other things, several portable engines, many tons of water-tube boilers, as well as reaping, mowing, binding and threshing machines.

That the imports or back-loads of the vessels from the Continent also pay well is proved by

the fact that the Lancashire and Yorkshire Railway Company alone have as many as twenty-four large steamers, aggregating over 21,000 tons, continually plying backwards and forwards between Goole and Holland, Belgium and Germany. At all events, they had them before the war, the traffic being mainly in merchandise.

There are extensive beds of lignite and peat in both Holland and Belgium, and there can be little doubt that the day is not far distant when both lignite and peat will be utilised. Valuable oils and alcohol have already been obtained in small quantities from these substances. The alcohol can be used in spirit engines and for general power working. Also, a wonderful fuel has recently been produced from peat. It burns with an intense heat, without smoke or flame, and practically without dust or ashes. The writer has seen experiments with this fuel, a sample of which is in his possession, and he mentions the fact to show that the subject is receiving from scientific men the attention which it deserves, especially as to the cost of its production.

Patent fuel is a large industry in both Holland and Belgium. The fuel is sold in the form of briquettes, composed of coal dust, tar, and lime, and makes a hot fire without much dust or ashes. This kind of fuel is also at present in use in the colliery districts of Wales, being found to be suitable for small tubular steam boilers, as it does not injure the tubes or choke them with ashes. Patent fuel is cheap in Wales, being sold at 15s. per ton, whereas suitable coal in the same district is 25s. per ton.

We found ourselves at about half-past one o'clock on a lovely summer afternoon off the famous old Dutch town of Terneuzen. Here we entered the sea locks of the great ship canal which was to carry us in four and a half hours to the city of Ghent in Belgium. Entering the locks we were soon raised to the level of the water in the canal, and proceeded on our journey in smooth water.

There are three sea-locks at Terneuzen, the largest and newest being 460 ft. long and 59 ft. wide. Ships up to 7,000 tons from South America, carrying bales of cotton to Ghent, pass through it constantly.

The sill at the lock gates at the sea end is 3 ft. lower than the inner sill, enabling vessels drawing 16 ft. of water to enter the lock at all times of the tide. The time of high water at Terneuzen is the same as that at London Bridge —a useful fact for mariners. All the lock gates, sluices and also the opening bridges over the canal are worked by electric power in the most up-to-date manner.

The date on the granite pierhead of the locks at Terneuzen is 1904, cut in large figures in the masonry. The original lock entrance, still in use, is much smaller and was built about ninety years ago. The canal was much narrower and not so deep then as it is now. In the year 1900 the traffic had increased so much and vessels of so much larger tonnage desired to use the waterway, that the two Governments of Holland and Belgium jointly decided to enlarge the canal. This was a huge work, which occupied eleven years, and the canal as it now stands was completed in 1911.

It would be interesting to know the cost of enlarging the canal, which must have been great. Owing, however, to its construction and enlargement being undertaken as a national work, the cost appears to have been a secondary consideration, the great point in view being to open up the city of Ghent, the capital of East Flanders, to the commerce of the world. This was done. In addition to large local and foreign trade on the canal, an immense business in bales of cotton was done through Ghent as a distributing centre with the United States, Texas, South America, Africa and the Congo, as well as with European countries, including Russia and the industrial districts of the Baltic.

In 1860 the number of vessels which used the canal was 357, having an average cargo of 138 tons per ship, the total for the year being 49,218 tons. With every increase of the facilities since that time up to the beginning of the war, there has been a steady increase in the tonnage. In the year 1913 the number of ships which used the canal was 1,398, with an average per ship of 759 tons, the total for that year being 1,061,425 tons. These figures show that the foresight, enterprise and large expenditure of the two countries have been fully justified.

But the canal was not only a commercial success, it was also a great engineering feat. It is located in the midst of low lying flat land, the banks being a few feet above water level. The country for miles around is not higher generally than the level of the banks, and in many places it is lower than the level of the water.

These low-lying lands were formerly subject to floods, which caused great injury and heavy losses to agriculturists and others. The country being liable to violent thunderstorms, the rivers Lys and Scheldt at such times become suddenly swollen and carry down immense quantities of water. In locating the canal this fact was borne in mind: the canal water-level was arranged to be the same as that of the normal water-level of these rivers where it joins them, the result being that the canal is fed automatically with water from the rivers without any storage reservoirs or pumping plant and pumping being required. In this way the water lost by evaporation, leakages, local water supplies, and the filling and emptying of the sea-locks when the vessels pass up and down, is replaced.

When the rivers are in flood the canal acts as a great relief conduit, conveying all surplus water to the sea through the locks at Terneuzen. This is a great advantage, as much land which was formerly of little use has now been brought into cultivation.

The canal, having the same water-level throughout its entire length, has also the advantage of not requiring intermediate locks. This not only saves labour and waste of water in times of drought, but also reduces to a minimum the delays to steamers passing up and down.

There are, however, two intermediate sets of locks in the length of the canal. These are at Sluyskill and Sas-van-Ghent, and are only intended for use in case of accidents or when floods bring down polluted water which might injure the canal and its local industries. In such cases the lock gates can be closed at once.

The prevention of floods enormously increased the value of land and property in the neighbourhood of the canal, and consequently the revenues derived from rents and taxes. In point of fact, the whole district through which the canal passes instead of being a wilderness was a "watered garden" producing large quantities of vegetables, bulbs and flowers. The land was also so well drained and hard that factories of various sorts sprang up in the vicinity of both banks of the canal. Amongst these are works for the manufacture of motor spirit, cement, sulphuric acid, manure, tar, railway sleepers, patent fuel, etc. The names of well-known British firms were to be seen amongst others as owners of wharves and works, busy and prosperous.

In the proposed improvements of British and Irish canals, in order to make them suitable for steamships, this canal might well be an excellent example to follow. A ship canal like the Terneuzen Ghent Canal, if made across Ireland through unproductive country such as that between Dublin and Galway, would drain large areas of peat bog and other waste land. Such a canal would give permanent employment to thousands of the labouring classes by the exploitation of the splendid limestones, marbles, brick clays, gypsum beds, and iron and coal mines with which the country is endowed. It would also shorten the voyage between London and Canada by about 500 miles, a saving in time of one day between Great Britain and North America. This is a subject which may perhaps receive the attention of the new Irish Government. It may not, therefore, be out of place to state here that there is in Ireland about a million and a quarter horse-power of water available for industrial purposes running to waste.

The banks of the canal are mostly sloped back, about one and a half to one, instead of being vertical like our British canals. The slopes are paved with flat stones or several courses of brickwork in cement, laid on a bed of concrete. These slopes are less expensive than vertical retaining walls, and are much better than vertical banks of clay, as they are not injured by the waves made by passing steamers, motor-boats and motor-barges, as clay banks are found to be. On the other hand, the slopes make the canal wider, and involve the purchase of more land for roads and towing-paths than is required with vertical banks or retaining walls.

Some of the older docks in Belgium have slopes instead of vertical walls, causing loss of valuable storage room on the dock roadways and wharves. All the new docks in Belgium are now, however, being built with vertical masonry walls, thus enabling ships to lie close to the quays and to discharge their cargoes more conveniently and rapidly. The construction of the large masonry piers and walls of the sea locks at Terneuzen was a work of some difficulty and presents one or two interesting features. For instance, the lock walls have the appearance of Roman tesselated pavement made of five-sided tiles.

It appears that the pier heads are of granite ashlar backed with concrete; the lock walls are built of concrete reinforced with blocks of 6 in. columnar basalt, pentagonal in cross-section and about 4 ft. long. The blocks were laid close together built into the concrete, their outer ends being set flush with the face of the wall and the top finished with granite coping. This forms an extremely hard surface for resisting the rubbing and bumping of the ships, and has a very pleasing appearance. The basalt blocks were imported from France and the cut stone granite from Germany. All the lock walls are built in the same way. In a few places where special wharves are now required retaining walls are being built of reinforced concrete, locally called *béton armé*.

The distance from Terneuzen to Ghent is about twenty and a half English miles, of which the canal proper is eighteen miles. Of the canal, eight and a half miles are in Holland and nine and a half in Belgium. In the Dutch portion the width of the canal is 220 ft., the width at the bottom being 78 ft. In the Belgian portion the width at water level is 318 ft., the width at the bottom being 154 ft. The depth of water throughout the eighteen miles of canal is 28 ft. 6 in.

The portion of the canal in Holland not being so wide as that in Belgium, crossing basins have been built at Sluyskil and Sas van Ghent, in addition to that at Terneuzen. With the excellent telegraphic and telephonic installations on the canal, the traffic can be worked on the absolute block-system if accidents, emergencies or abnormal increase of traffic should make it desirable to do so.

The speed of steamers and motor-boats traversing the canal appears to be about six miles per hour. The speed of the steamship "Wharfe," including stops, between Terneuzen and Ghent, averaged five miles per hour. The speed of the old canal boats, horse-drawn, on British canals is about two miles an hour. There are eleven opening bridges over the canal, two of which deserve notice. One carries a public road and the other a railway. The two main girders of each bridge are of steel, latticed, in one span of 85 ft.

Here is a description of the railway bridge at Selzaete; but both bridges are practically alike.

Each main girder has its lower flange at the west end, continued over the abutment, but, instead of being continued horizontally in a straight line, it is curved upwards in the form of a semicircle to about the height of the top flange, the end of each girder thus being semicircular. Near the top of the semicircular curve a powerful pin with a tension bar attached to it is fixed. To open or raise the bridge, the tension-bar is pulled horizontally in the direction of the abutment by electric power operated in a signal-cabin at the end of the bridge. This tilts up the entire bridge on its curved end, thus allowing a vessel to pass through. The operation of opening or closing the bridge is so rapid that it is only a matter of seconds. The signals on both the railway and the canal are under the control of the one signalman in the signal-cabin at the bridge, who raises and lowers the latter as required.

The voyage along the canal from Terneuzen to Ghent was extremely interesting. We left Terneuzen at two o'clock in the afternoon of June 12th in extremely hot weather, with everything in our favour for a splendid view of the country, the people, and the various industrial works.

The first town we came to was Sluyskil, where there is a passing basin and a large swing-bridge over four spans. Here on the east side the canal widens out into two branches. There is also a short piece of a third branch, partly made.

At this place we first saw the working-men in their blue jackets and sabots. The workmen's cottages, of about three rooms, along the banks of the canal looked picturesque with their red-tiled roofs and shuttered windows painted green and white. Everything about them, including the wooden palings, the footpaths, even the shrubs and flowers, looked painfully clean and neat.

The first reach of the canal for about four miles is quite straight and presents a noble appearance. This reach runs from north to south, the north end being at Terneuzen.

There are good cart roads along the canal banks, that on the west bank being paved with 6-in. square stone blocks.

The roads are lit throughout the entire length of the canal with incandescent lamps of twenty-five candle power, placed 164 yards apart on the straight portions and 82 yards apart on the curves.

There is telephonic and telegraphic communication with all bridges, locks and signal-cabins. Electric cables convey current for operating the locks and bridges and for industrial purposes where required. There are electric cranes and transporters for dealing with traffic at the various wharves along the canal.

The rule of the road for vessels is to keep to the left. Imagine, therefore, the horror of the writer, when standing on the bridge with the captain, on seeing a tug with four barges coming towards us on the same side as ourselves! The captain merely observed that some of the masters of vessels were not very particular, and, as the canal was wide enough, he simply steered his 1,000 tons steamer to the right until they had safely passed.

Great numbers of birds are to be seen along the canal, especially cranes, probably because of the marshes in the vicinity.

On arriving opposite the town of Sas-van-Ghent we were at the boundary between Holland and Belgium. Here we had to stop and make fast to the Custom House jetty while the captain and the chief officer went ashore to make affidavits as to the numbers and identification of the passengers and crew. This is done at the Custom House, a long one-storied red brick building on the east bank of the canal.

This building is placed at the centre of a carefully-defined boundary line, which is supposed to cross the canal diagonally from a large cast iron pillar on the east bank to a similar pillar on the west bank. These pillars are about half a mile apart, one being in Holland and the other in Belgium.

"Protection" is strictly enforced between the two countries, and the questions to be answered by officers of trading vessels are very searching. For instance, one of the most important questions was as to whether any person on board, including the crew, the officers and the passengers, had bought any new clothes during the voyage, and if so, what became of the old clothes? This seemingly silly question was to find out if any infectious disease was on board, and to prevent it from being brought into the country.

In addition to full particulars of all wine, spirits, beer, tobacco and general contraband on board, the quantity of tobacco in each smoker's pouch had to be stated in writing.

We arrived at the Congo Wharf, Ghent, at ten minutes past six o'clock in the evening of June 12th, after a most enjoyable passage.

Ghent.

Immediately the ship had been made fast to the wharf she was boarded by a smart stevedore

with a large gang of ship labourers, and the unloading of the cargo began.

It was positively refreshing to see the energetic way in which the Belgians went to work—no fuss, but methodically, and in less than half an hour they had all the deck load removed to the quays. All general merchandise was unloaded at the Congo Wharf, and the ship was then brought to the opposite side of the great docks, where the coal cargo was removed by electric transporters, and the ship made ready by noon next day to receive her return cargo for Goole.

The dock accommodation at Ghent is very extensive and up to date, but the constantly increasing traffic has made it necessary to build further extensions. New docks and quays of great extent with large stores and sheds have just been completed. These works were partly built by the Belgian Government and partly by the great shipping companies of Belgium, the Agence Maritime of Ghent and others.

The man of "push and go" of this business is M. Edmond Minne, the general manager of the Agence Maritime, to whose energy and ability the city of Ghent owes much.

M. Minne, who is also the Consul for Cuba, states that two million bales of cotton per annum are imported into Ghent by the companies with which he is connected. This cotton is exported from Ghent to various parts of Europe, including Russia and the spinning centres of the Baltic.

Cotton is also largely used in the city of Ghent, where there are a million and a half cotton and flax spindles at work, in addition to fifty thousand looms, the whole employing about fifty thousand hands.

Ghent, with its population of two hundred and twenty thousand, is rapidly becoming a great manufacturing and mechanical engineering centre. Also, its position at the confluence of the two rivers, Scheldt and Lys, has made it truly a paradise of flowers. Many of the beautiful plants in our gardens and conservatories come from there, such as bay trees, laurels, azaleas, aspidistras, orange trees, araucarias and palms, large quantities of which are imported annually into Great Britain.

There is an excellent system of electric tramways throughout the city and suburbs, with frequent service and cheap fares. The road waggons, drawn by horses for conveying heavy loads, have generally only three wheels one in front and two trailers.

The town of Ghent is so intersected with canals that it forms practically thirteen islands, with fifty-eight bridges. Perhaps this, with the consequent want of space, accounts for the great bulk of the streets being so narrow. The pavements and footpaths are mostly paved with pebble stones, which makes walking uncomfortable. The main thoroughfares are, however, well and properly paved with smooth surfaces.

The railway stations are imposing buildings, and well designed for their purpose. The permanent way consists of flange-rails laid on small wrought-iron plate-chairs bolted to half-round sleepers. The ballast used was mostly ashes, but in some places it was of limestone gravel.

The great main lines were in good working order when the writer saw them. The coaches were first, second, and third class; few people travelled first, the coaches of which were excellent. The second and third classes were not nearly so good as English coaches; they were not cushioned except on some of the main lines. The branch lines were by no means well maintained, either in permanent way or rolling stock, with the exception of the engines, all of which on all lines were good. The railway fares were too high, the first class greatly so; and although in all cases passengers could obtain a fairly cheap season ticket by paying considerable sums, a poor man could not do this. In fact, the whole railway system required revision apparently, but could no doubt be made to pay well with cheaper fares.

Railway time in Belgium begins at twelve o'clock midnight, all the time-tables being worked out for twenty-four hours. A train which in England would start, say, at 9.45 p.m., would in Belgium be tabled to start at 21 hours 45 minutes. In restaurants, hotels and private houses Greenwich time is used.

Ghent being an industrial flax and cotton spinning centre, it was interesting to compare the dresses of the women and girls going to and from their work with those in Lancashire and the north of Ireland. In the latter two districts there is not much trouble taken to dress neatly during working hours, and any person who has stayed in Lancashire hotels knows the noise the clogs of the workers make on the street pavements at five o'clock in the morning. Ghent has none of this, so far as the writer could see.

There was the inevitable shawl over the head in many cases, although it was summer weather; but the greater number of the girls were neatly dressed with smart French boots or shoes, neatly trimmed hats, and up-to-date blouses and jackets.

COURTRAI.

Courtrai, in West Flanders, stands on the River Lys, and has a population of about thirty-five thousand. Its principal business is the growing and weaving of flax, the soil, water and climate being singularly suitable for the cultivation of the flax plant. So great is the quantity of flax produced that, in addition to supplying its own wants, it is able to supply other places, including the North of Ireland (the city of Belfast, in particular), with a large proportion of what is used there. The flax grown in the Courtrai district is reputed to be of the highest quality known in the trade. This is supposed to be due to the waters of the River Lys, which, rising in the north of France,

carry down with them to the swampy lands surrounding Courtrai various effluents from the dyeing and other chemical works along its banks. There is a colony of Ulstermen at Courtrai, numbering about three hundred, whose business it is to purchase and supervise the growth and steeping of the flax before it is despatched to the North of Ireland markets.

The Belfast buyers call the River Lys "The Golden River," because the flax grown on its banks commands a higher price than any other known.

The writer saw the previous year's growth undergoing the process of "retting," or steeping, in crates on the banks of the Lys. The land was very flat and the river wide and shallow, except in the centre. The crates were held in their places by stakes driven into the ground, so that the water could permeate the flax bundles. Gangways were made of wooden planks from the top of the banks, leading down towards the centre of the river at intervals between the crates. These gangways were for the purpose of inspecting the flax, so as to decide the length of time required for the process of steeping. When the flax is sufficiently steeped it is taken out and piled in stooks to dry. In many cases it is kept in store during the winter and put into the river a second time the following season, after which it is taken out and dried on cone-shaped supports. When the flax is quite dry it is stored for a time and subsequently sent to the scutching mills.

Courtrai flax is noted for its great tensile strength, fineness and colour. The writer has a sample of the flax stalk, in its raw state, which is as difficult to break as a piece of twine. This is at first surprising, seeing that the stalk is only as thick as an ordinary hay-stalk; but inside the husk there are twenty to thirty white threads like silver grey hairs, fine and strong. These are the flax threads from which the linen is made.

The crates of flax when undergoing the process of steeping extend for miles on each bank of the river, which is of great width. The writer was told that steeping the flax in the waters of the Lys made it soft and flexible without injuring its texture or reducing its tensile strength. Several factories were in full work, employing large numbers of hands in preparing the flax for market, notably that of "The Linen-thread Company of Courtrai."

Lace-making is also carried on in the district, some six thousand women being employed. Large quantities of lace were to be seen in the fields "bleaching" along with the linen. Linen, woollen and cotton weaving mills, tobacco factories, sugar, soap and paper-making works employ thousands of hands.

The writer is much indebted to M. Deschoemaeker, of Courtrai, whom he had the good fortune to meet there, for a great deal of the above information, and for his kindly advice and courtesy to a stranger in a strange land.

It is remarkable that Ulster should now largely depend upon a town in Flanders for the flax used in one of her principal industries considering the large quantities she grows herself. Yet this is so, for practically all the large flax mills in the North of Ireland, including the York Street Spinning Company, Belfast, which employs thousands of hands, have extensive stores and offices at Courtrai, and large continuous business is done between the two places. It must not be forgotten that there is a sort of affinity between the two peoples. The Flemish people who settled in Ulster in the sixteenth and seventeenth centuries were the ancestors, to some extent at all events, of those who are now the workers in Belfast. Although Flemish weavers were introduced into England in the reign of Henry III at the beginning of the thirteenth century they appear to have largely employed their talents in the North Country; and even now Leeds in England, Dundee in Scotland, and Belfast in Ireland may be said to be the principal spinning centres in Great Britain.

Wherever the Flemings went they seem to have brought good luck. Their careful, thrifty habits, steady perseverance in their work, the ingenuity and art displayed in its execution—all have been of great value to Great Britain and Ireland. Who has not admired the beautiful tapestries of the sixteenth and seventeenth centuries depicting historic battle-scenes, many of them the work of Flemish weavers? Surely it is not straining the fact to say that Britain in helping Belgium now in her hour of need is doing nothing more than making some return for the prosperity which the Flemish people have brought to this country wherever they have settled.

There are many places of historic interest in Courtrai; but the great Battle of the Spurs, which took place on July 11th, 1302, overshadows them all. In this battle twenty thousand Flemish, mostly weavers of Ghent and Bruges, defeated and put to flight seven thousand knights and noblemen of France and forty thousand infantry. After the battle some hundreds of gilt spurs were found on the field and kept as trophies, to be handed down to posterity.

The Flemish were under the command of Guy de Namur, to whom a golden (gilt) statue has been erected on the Boulevard de Groeninghe. The gardens along the boulevard are beautiful. Some of the flower-beds surrounding the statue are planted to represent his coat-of-arms, the different colours of the flowers being produced in accordance with heraldic requirements. The gratitude of the people still impels them thus to keep their great leader's memory green.

The working classes are very proud of the fact

that they were able to give so good a thrashing to the very men and their leader who had previously beaten and oppressed them. Let us hope that history will repeat itself in the near future with the present ruthless invaders of Belgium!

There are, as usual in Belgian towns, some fine old buildings in Courtrai, including the town hall, with splendid frescoes in the alderman's room representing events in the history of Flanders. A great picture by De Keyser, in the museum, represents the Battle of the Spurs.

There is a street bridge with a very old round tower at each end. These towers were probably for defence in ancient times, but are now used as a museum. A golden crucifix seen from the street is let into a "slit" in one of the towers.

Amongst the statues in the town there is one erected to Jean Palfin, who invented the forceps.

A racecourse in the suburbs appears to be well patronised by the working-classes.

The streets of the town are generally paved with six-inch square stone blocks, which caused much jolting when driving over them in the one-horse old-fashioned victorias in use.

The post-office is a fine stone building with a large square tower with louvres. The whole of the four sides above the roof are covered in regular rows with the insulators of telephones and telegraph wires, in different colours, which gives the whole a peculiar appearance. The wires are evidently conveyed to the instruments through the louvres.

The railway station is mostly a long one-storied building, with several lines of rails and platforms. Courtrai is an important junction for north, south, east and west trains so important that the aviators of the Allies have recently dropped bombs upon it which caused great injury, especially to the railway lines. As in other towns of Belgium, dogs are used for hauling light carts, but horses are used for heavy work.

The people appeared to be of the well-to-do class—well dressed and well fed. The hotels are properly managed, clean, and the food and drinks good.

Antwerp.

The city of Antwerp is, next to Brussels, the largest town in Belgium. It is situated on the River Scheldt, about fifty-three miles from the sea, and has a population of about three hundred and twenty thousand. The fortifications, forts and walls with gates, which practically surround the city, were found to be too near thereto to protect it against modern artillery. Some years ago the late King Leopold began to build new and more distant forts and defensive works, which were in progress when the present war began.

The city is well built, with broad streets planted with trees along the wide, smoothly paved footpaths. The streets are lit with powerful electric lights; and electric tramways, with frequent services and cheap fares, run through the city and suburbs in every direction.

The river opposite the town is about four hundred yards wide and very deep. The quays are many miles in length, and steamers can come up close to the town. Excursion steamers ply across and both up and down the river to places of interest at cheap fares. The view from the landing-stage, near the offices of the Lancashire and Yorkshire Railway Company, on the Quay Jordaens, is interesting, showing the great width and length of the river, and the steamers constantly arriving and departing for all parts. There are no less than eighty-nine lines of steamers, including ocean-going vessels, which make Antwerp one of their most important ports of call for the Continent of Europe.

The railways have four main-line passenger stations in various parts of the city. The central station, at the top of the Avenue de Keyser, is a splendidly built structure which cost about £1,500,000 sterling.

The beautiful bronze entrance gates of great size, are said by the newspapers to have been removed recently by the German invaders to melt down for making heavy guns. This piece of vandalism was only to be expected, seeing what they have done in other towns in Belgium.

The public buildings of Antwerp are of the highest historic and architectural value. The cathedral spire, a beautiful work of art, is one of the first objects to be seen by vessels coming up the river. It is about 470 ft. high, and the building covers an area of 70,000 sq. ft. This is more than that covered by Cologne Cathedral perhaps for this reason the Germans may destroy it! The foundations were laid in 1352, and the structure occupied nearly two hundred years in building.

Antwerp is, of course, a great centre of art. The magnificent pictures in the cathedral and many other public places, as well as the buildings themselves, show this; and Rubens, Van Dyck and other great artists were born there.

As an industrial centre the city has a great reputation: the diamond-cutting trade alone has made it known all the world over. The industries include anything "from a needle to an anchor." In proof of this, steel rails, girders, rolled joists, and every kind of heavy iron-work are made there. The following incident will speak for itself. A Belgian gentleman gave the writer a small object, in a piece of white paper, which was too small to distinguish with the unaided eye. On putting it under a powerful magnifying glass it proved to be a very small screw with a cylindrical head and a slot in the top, the thread being complete and all beautifully finished in bright steel. The gentleman was the owner of a works in Antwerp which made thousands of similar screws for watch-making.

The Zoological Gardens well repay a visit.

Instead of being placed in the suburbs, like most of the "Zoos" which the writer has visited, they are situated in the town at the head of the Avenue de Keyser, adjoining the central railway station. They cover a very large area, but are so well arranged that there is no loss of space, the land being almost wholly covered with fine buildings; but the walks and passages are all of ample width. The collections of wild and domestic animals, reptiles and birds have the reputation of being the finest in Europe.

The aquarium was a delightful place, cool and interesting, as the weather was very hot, the sea-horse being "stabled" in one of the tanks. The buildings for housing the animals were architecturally superior to similar buildings in other places. The concert-hall, restaurants and places of entertainment seemed to be arranged to tempt visitors to remain a whole day in the gardens, and this they appeared to do. Many fine monuments and splendid pictures were also to be seen in the entrance hall.

For moving about the city there are plenty of taxicabs. The electric tramways, however, are more popular, as the penny fare pays for a long journey. The tramways are continued along the quays and docks, past the berths of many lines of steamers well known in England. Indeed, the quays remind one of the London docks and the Thames.

When returning to England the writer left Antwerp by one of the Lancashire and Yorkshire Company's fine steamers for Goole. Going down the Scheldt, a splendid view of that river and the quays and docks along it was to be had. One peculiarity was that some of the shed roofs on the quays were made flat for promenades, and had parapets all round. These roofs were converted into public gardens, with shrubs and flowers planted in boxes and semi-barrels, with seats for the public, who could be seen enjoying the fine views of the river and shipping, and obtaining a breath of fresh air. The roofs of the old forts not now in active service, were also utilised for the same purpose.

There is an excellent service of trains between Antwerp and Brussels, the journey of thirty-one and a half miles being run in about half an hour.

The writer's thanks are due, and are hereby tendered, to the officers of the Lancashire and Yorkshire Railway Company for their courtesy and kindness both in England and Belgium; and particularly to his old friend Mr. John Dowling, the London and Continental Traffic Superintendent, who, he regrets to say, has recently "passed over to the majority."

PAPER-PULP MANUFACTURE IN MYSORE.

According to a report recently presented to the Mysore Economic Conference, investigations into the practicability of the manufacture of paper pulp in the State are being proceeded with in several directions. The forests have been explored for suitable raw material by special officers deputed for the purpose, and a qualified technical expert, Mr. Raitt, has been engaged to conduct tests on samples of grasses and bamboos locally available, with a view to arrive at an estimate of the working costs under factory conditions. An agreement has been concluded with one of the factories in India to get paper manufactured out of twenty tons of crushed bamboos sent from Mysore. The resources in Mysore, both in grasses and bamboos, appear to be ample for the manufacture of pulp on a commercial scale. The Mysore district is specially rich in large grass areas, and eight forests, of an aggregate extent of 456 square miles, have been explored during the year. There are at present two cotton-mills in Bangalore, and the question of starting another mill has been under the consideration of the committee for the past two years. It was at first contemplated to establish the mill at Davangere or Harihar, but subsequent inquiries have proved that Bangalore was the most suitable place The electric energy available at Bangalore would offer a convenient source of power, and facilities for obtaining labour would be greater there than elsewhere. In regard to the question whether there is room for an additional cotton-mill in the State, the report prepared by the Director of Industries and Commerce offers a conclusive answer. It has accordingly been decided that a mill with 2,500 spindles and 500 looms, with an estimated annual outturn of 32 lakhs of lbs. of yarn and 18 lakhs of lbs. of cotton cloth, may be established with reasonable prospects of success. The capital required to run the mill is about 16 lakhs of rupees

THE PRODUCTS OF COAL DISTILLATION.

In a paper recently read before a conference at Cardiff, Mr. W. J. A. Butterfield discussed several important aspects of this question, and gave some valuable statistical information.

The output of coal in the United Kingdom in 1913 was 287,430,473 tons; in Germany it was 188,485,000 tons, but in addition to this 86,093,000 tons of brown coal or lignite were raised. The United Kingdom retained for home consumption 189,092,369 tons; Germany retained about 155,503,000 tons, and 93,455,000 tons of brown coal, part of which was imported. These figures show a mean consumption of coal of 4·108 tons per head in this country, as against 3·68 tons of coal and lignite in Germany, and as the coal consumption may be taken as an index of the industrial activity of a country, these figures are satisfactory.

With regard to the manufacture of gas and coke, it is estimated that in 1913, 37,483,944 tons of coal were used in this way in the United Kingdom, something over 16,000,000 tons being carbonised in gasworks. In Germany the total quantity carbonised was 62,613,000 tons, only about 9,000,000

tons being used in gasworks. While 42·7 per cent. of the coal carbonised in this country is treated in gasworks for the production of coal gas, in Germany the corresponding figure is only 14·4 per cent., the greater quantity being treated for the production of coke.

Owing to this larger proportion being carbonised in ovens in Germany, the quantity of some crude products which are of primary importance in chemical industries, such as benzol, is very much greater in Germany, considering the total amount of coal carbonised, than in the United Kingdom.

The recovery of benzol has now become a matter of national importance, since toluene, which forms from 10 to 25 per cent. of the benzol, is in great demand for the manufacture of trinitrotoluene. In recovery-oven practice the gas is stripped of all the benzol content, but in gas-making only the toluene content and the benzol is removed permanently from the gas.

Benzine, toluene, and xylene, which are obtained from the heavier fractions of benzol and the lighter fractions of naphtha, are the raw materials from which many nitro-compounds are produced for the manufacture of explosives, and for the preparation of bases, such as aniline, toluidine, xylidene, etc., which are the starting-points for the manufacture of large classes of dye-stuffs and drugs. Congo red, indigo, many aniline dye derivatives, fuchsine, and eosine, are among the most important of the derivatives of the benzine hydrocarbons. The heavier oils, too, are important. Phenols yield valuable disinfectants, and phenol itself is the raw material for the manufacture of salicylic acid, many dye-stuffs, and the important explosive picric acid (lyddite).

COMMERCIAL SITUATION IN JAPAN IN 1914.

Naturally the war has affected Japanese trade very seriously, and from the figures given below, writes H.M. Commercial Attaché at Yokohama, it will be seen that there has been a great curtailment in the volume of business transacted; yet a large part of this reduction must be ascribed to causes unconnected with the war, and it will probably be found that, although Japan is actually one of the belligerents, the effects produced on her trade have on the whole been less than has been the case with many neutral countries.

The value of the import and export trade of Japan, including Formosa and Korea, for the years 1912 to 1914 is shown in the following table:—

Imports.

As regards imports there is no question that even without the war there would have been a very serious decrease. Up to the end of July that decrease was no less than £3,363,300, and it would have grown proportionately greater as the year advanced. This was the natural result of the Government's policy of economy and retrenchment, which meant the curtailment or postponement of many public works. There had also been a general feeling of depression which was reflected in the placing of fewer orders for goods from abroad, while the fact that the rice and sugar crops in Japan and Formosa respectively had been good accounts for a big reduction in the imports of these two staples. It would hardly be fair, therefore, to ascribe to the war the whole or even the greater part of the falling-off in the import trade. It is true that the difficulties of exchange, high marine insurance rates, and the prohibition of export of many articles from Europe seemed to paralyse trade for a while, but as confidence is gradually returning, inquiries are beginning to dribble in, and although the embargo on many exports is naturally making trade with the United Kingdom impossible in such goods, there is a feeling that the import trade will soon begin to show signs of recovery. Stocks, generally speaking, are getting low, and dealers who have been pursuing a hand-to-mouth policy will soon have to make up their minds and place their orders regardless of the fact that prices have gone up.

Exports.

As regards exports the position is very different. In this case the direct effect of the war is undoubted. Raw silk and silk products are Japan's most important exports. In ordinary years they account for nearly 40 per cent. of the total shipments abroad, and as silk is a luxury, the demand for which must necessarily be greatly curtailed in times of war, and as, moreover, next to America, France is the greatest buyer of Japan silks, the declaration of hostilities produced a crushing effect on the silk market. Prices of raw silk, which had been round about 1,000 yen per picul (about £102 per 133⅓ lb.) in July, dropped till they fell below 700 yen per picul (about £71 10s. per 133⅓ lb.), but although America continued to make large purchases at these reduced prices, the total export shows a large falling-off both in quantity and value. Up to the end of July there had been an increase in silk exports over the preceding year of about £1,380,000. By December this had been converted into a loss of over £2,760,000.

Year.	Imports.	Exports.	Total.	Excess of Imports over Exports.
	£	£	£	£
1912	67,850,587	55,897,093	123,747,680	11,953,494
1913	79,482,751	66,451,893	145,934,644	13,030,858
1914	64,612,000	62,259,100	126,871,100	2,352,900

As regards other exports it cannot be said that they were very seriously affected. For the first few weeks after the opening of hostilities there was little doing, but recently a large development has taken place. This is not apparent in the 1914 returns as the orders have only recently been booked, but there is little doubt that, with the exception of silk, Japan's export trade will benefit on account of the war. The chief obstacle at present is the lack of shipping facilities, but there have already been large shipments—with more to follow if space is available—of rice, green peas, oats, and barley to Europe, wheat and bran to Australia, and Manchurian maize from Kobé to the Pacific coast. Nearly all this business is exceptional and can only be ascribed to the war. Again, large orders are being booked for toys, cheap glassware, acetic acid, sulphuric acid, etc., all of them lines in which Japan has a chance of pushing her goods while other competitors are out of the field.

TRADING DIFFICULTIES.

Certain trades have suffered from inability to get the necessary chemicals, such, for instance, as the match industry, which had to curtail production on account of shortage of supplies of chlorate of potash. Others, like the cotton-spinners and the copper-mine owners, were badly hit by a tremendous drop in prices. The farmers, with rice quotations falling day by day, became increasingly despondent and could not afford to buy fertilisers.

The troubles of the cotton, copper, match, and other groups were gradually surmounted. The semi-Government banks tided them over the most dangerous time, and fortunately prices soon began to recover, so that at the close of the year cotton-mills and copper-mine owners were once more in a state of prosperity. The rice and silk problems, however, presented far more difficulty. Measures for relieving the situation were brought forward by the Government, but before they could be passed the Diet was dissolved. Later on, in February, 1915, the Government by Imperial Ordinance authorised the Minister of Finance to make purchases of rice in such quantities and at such times as seemed suitable. The effect of this Ordinance has been to bring about the result which the Government wished, namely, to force up the price of rice to a level of 15 yen (about 31*s*.), which they considered is remunerative to the farmer, but the measure has been much criticised, both on economic and political grounds.

THE RUSSIAN SOLDIER.*

I have seen a good deal of the Russian soldier during my residence in Russia. I used to visit the barracks and the sergeants' messes, and I spent some weeks in camps of exercise with the Astrakan regiment of the Russian Army—the 12th Grenadiers —of which the late Emperor was Chief. The regiment was originally raised by a Scot named Roman Bruce, eldest son of one William Bruce, who migrated to Russia in Cromwell's time; and the regiment was commanded, when I was with it, by a Tartar colonel, a Mohammedan. I used to find the Bible very much in evidence in the sergeants' mess, and the knowledge which the common Russian soldier possessed of the poets of his native land (Pushkin and Lermontoff, Nekrasoff and others) was simply wonderful. It is quite a mistake to imagine that Russian soldiers are as a rule ignorant and illiterate. This is not true even of the majority, and many of them may be described as well educated. But to whatever class the rank-and-file belong they make the best of things, and are wonderfully cheerful and contented. Though their pay is miserably poor (about 1½*d*. a day) and their work often very hard, you never hear them growsing or grumbling. In pluck and, I may add, in capacity for never knowing when they are beaten, they resemble our own soldiers; and as to their devotion to their native land—Holy Russia—and their Little Father—the Emperor—there is not the shadow of a doubt. They are ready to give their lives freely for both, and with them war against the Teuton enemy is a religious duty. It is strange how history repeats itself. In the battle of Kunersdorp (fought on August 1st, 1759, against Frederick the Great) this Astrakan regiment lost thirty-two officers and more than half its rank-and-file; but it was mainly due to the charge they made that the victory was won. It may be recalled that this battle of Kunersdorp first resulted in an apparent victory for the Prussians. They captured ninety guns, and drove the Russians from point to point of their position to the extreme spur or last ledge of a long ridge of low hills. Here, as evening fell, the Russians made a final stand, but Frederick was so sure of victory that he sent off a despatch to Berlin announcing the rout of the Russians (just as William II. is so fond of doing now). But "he laughs best who laughs last," says the Russian and English proverb, and the Russians had the last and best laugh. Next morning, when the Prussian battalions renewed the attack and charged up the height against the Russian position, they were received with such a murderous fire that they were driven back in all directions. The Russian soldier is never so dangerous as when standing at bay, like the bear of his native wilds, and on this occasion the Russians "greatly stood at bay." In vain the Prussians again and again renewed the assault; they fell back in confusion each time, until at last the Astrakan regiment, the Grenadiers, charged down and routed them completely. The Prussian King, Frederick the Great himself, was severely bruised in this fight (having had two horses killed under him), and was very nearly taken prisoner. The Prussian loss in killed and wounded amounted to 10,000 men, and they lost 178 guns, and some 5,000 surrendered as prisoners of war.

* Extracted from a paper on "India and Russia," read by Dr. John Pollen, C.I.E., I.C.S. (retired), before the East India Association.

The memory of this achievement still lives in the Astrakan regiment, and is cherished by the rank-and-file.

Jubilant in victory, inclined like his Indian and Irish comrade to exaggerate deeds of military daring and prowess and acts of individual heroism, the Russian soldier is seldom depressed by defeat, and is always ready to account for or minimise disaster, by declaring that the enemy was from twice to ten times as strong as himself, and that defeat was due to no fault or defect on his own part. This is, perhaps, only saying that the Russian soldier is human, but I think it ought also to be recorded and remembered that he is Christian and humane. His foes need fear no demoniacal mutilation, no dastardly cut-throat treachery, no Tartar or Teuton atrocity at his hands. His religion—nay, his very superstition if you will—has taught him the meaning of a fair field, and in dealing with Russians Christian nations ought not to forget that they have to do with intensely earnest followers of the faith they themselves profess.

But in addition to being Christian the Russians are a "singing nation," and in that fact lies much of their strength and cheerfulness. The way the Russian soldiers burst into song as they march along, struggling against vile weather and worse roads, is as inspiriting as John Peel's "Tally-ho!" As has been well said, there is perhaps no country in the world where love of song may so justly be claimed as a natural characteristic as in the great Russian Empire. Russians never sing coldly, and absence of feeling (the "teacher's despair," as it has been called) is a fault rarely met with amongst them. When they sing they put their whole heart into the song, and their sweetest songs are often those that tell of saddest thought. The Russians also love dancing, and they will dance to the concertina or the drum if no other musical instrument be available, and their country dances often reminded me of the hill-dances I have seen in India. But in Russia the women begin dancing first and the men join in afterwards, whereas in India it is just the other way.

Time would fail me to tell of the many other points in which resemblances can be traced between India and Russia; but I may just mention one great characteristic, namely, the spirit of brotherhood and equality which prevails. In the free and familiar way in which orderlies talk to their officers, and in which even Grand Dukes are addressed and accosted, in the easy and unconcerned manner in which the peasant will sit down beside the grandee on the roadside benches or on board the river steamers, or stand or kneel beside him in church, one recognises the democratic idealism of the East.

It is with a people characterised by the qualities I have endeavoured to describe that Great and Greater Britain and India are now happily in firm alliance, and from this alliance I for one look forward with confidence to great and abiding benefits both to the East and to the West, and especially to India. I have never believed in the policy of buffer-states and bottled-up harbours; and following Sir Alfred Lyall and others who knew India and her true interests well, I have for the last twenty-five years consistently advocated combination and co-operation with Russia. Until the Crimean War Russia had always been our friend and ally, and during the Crimean War it must be recalled the Emperor Nicholas protected British colonists and merchants in Russia, and allowed the British in Moscow to pray in their church there that Queen Victoria might have victory over all her enemies. Russia has always proved a generous foe and, war or no war, has never repudiated her debts.

She is in truth a great democratic Power, and she has saved Europe more than once from tyrannous foes. She has given peace to Central Asia, and is helping to revive its cultivation and civilisation. And now an abiding alliance between her and Great Britain will probably prove the best safeguard of the rights and freedom of the peoples and nations of the East, while securing the populations of the West from future wars of aggression and destruction.

ARTS AND CRAFTS.

The Slav feeling for Design.—The exhibition of Ivan Mestrovic's works at the Victoria and Albert Museum has raised a storm of criticism and approval which has attained quite large dimensions and attracted considerable attention. That is perhaps not to be wondered at, for the sculptures are decidedly unusual and original—and a few of them show characteristics which, whatever we may think of them in the work of the Slav master, would undoubtedly not bear repetition at the hands of the British students who, especially at this season of the year, flock to South Kensington. There is, however, one aspect of his work which has been but slightly touched upon, and that is its decorative quality. We have all been learning of recent years by the aid of exhibitions, as well as through books and travel, that in the minor arts the Slav is able to give a good account of himself. Some of us have come to realise that a good deal of embroidery and other craftwork which we had been accustomed to call rather loosely Hungarian, though it came indeed from the Austro-Hungarian Empire, was the work of neither of the dominant races there. It is due not to Teutons or to Magyars, but very largely to Slavs, though the work of the Rumanes of Transylvania has also to be taken into account. That being so, it is not surprising that the work of a Slav sculptor—a Serbo-Croatian by race, a native of Dalmatia—whose earliest training had been in woodcarving, should be pronouncedly decorative in feeling. This feeling is most strongly marked in his bas-reliefs where the traditions of his woodcarving technique still cling to him. The sheer cut lines of the outline in themselves suggest

the flatness of decorative convention, whilst the treatment of the details shows over and over again the artist's sure instinct for design. It has been suggested that the treatment of the wings of the angel in the Annunciation panel bears traces of his early training; it certainly shows, in its curious likeness to the wing of a Chinese embroidered butterfly, a distinct preference for decorative form. Again, the reverse of the medal in honour of the victors in the first Balkan War, with its central colossal winged figure holding in outstretched hands the heroes' crowns over the two rows of kneeling figures who, with bent heads and spears laid on the ground, await the reward of their deeds, is a fine piece of decorative composition. The large vases exhibited are also very satisfactory in shape, while the band of figures with lifted arms encircling one of them is an ideal decoration for a vase with a fairly large bowl and a slim neck, as it not only forms a pleasing ornament in itself but also helps the shape of the vessel it adorns. It recalls a Greek device but there is no servile imitation about it. The work for the temple at Kossova is on so large a scale, whilst the wooden model is so small, that it is difficult to tell how far the sculptor's decorative instincts would hold their own in his architectural work. However that might be, the works exhibited at the Victoria and Albert Museum prove his feeling for design and have very considerable value for decorators and designers.

Mr. Carter Preston's Polychrome Models.—It seems at first sight a very far cry from the heroically monumental work of Ivan Mestrovic to Mr. E. Carter Preston's polychrome models and statuettes, none of which are so much as two feet high, whilst few of them are very serious in intention. On the other hand, the artist's method of cutting his shapes with a saw and building up his models by the super-imposition of thin slices of wood does in some measure recall the sheer cutting of M. Mestrovic's reliefs, whilst his tendency to seek his inspiration from eastern sources forms another point of contact. For the rest, however, Mr. Carter Preston's technique seems to be really the outcome of a desire to express rather more than he found himself able to do by the simple process of cutting out figures in silhouette. This last method has been adopted by many artists trying their hands at toy-making, but Mr. Carter Preston has arrived, by the carrying further of it, at a mode of expression all his own. His technique allows him to reproduce exactly as many copies of his original as he considers advisable, and it further stamps his work with an unmistakable character. The wood is naturally worked in planes, and the final result is a certain squareness which in able hands has been made remarkably expressive. The only thing against it is that (especially in the case of some of the toys, though it holds good of the more serious models too), it gives one the feeling that the figures ought to be movable. It seems as if the various layers of wood must have been so put together as to allow of some play even in the case of the solid caricatures and the like; whilst the toy animals, which in many instances do move their ears or perhaps their legs, ought to quiver in every limb. The mere fact, however, that they give this impression is a striking proof of their go and vigour. The colouring of the figures is generally very happy, and such pieces as the Sun Dragon, the Aztec paperweight and the Gryphon are very full of meaning, whilst the caricatures of Marshal von Hindenburg, Mr. Lloyd George, General Joffre and the Gallic cock, Lord Kitchener and the British bull dog, are most amusing. When it comes to the studies in symbolism, the results are not quite so uniformly satisfactory. Heligoland and the Bosphorus are full of interest, but one hardly feels that the figure entitled "Who is this that cometh from Edom?" expresses quite what it was meant to convey. It represents, indeed, an Oriental potentate striding along in his majesty, clothed in garments which prove on examination to yield a wealth of symbolic meaning, but for all that the model appears rather lacking in impressiveness. It would seem that the method, eminently satisfactory as it is for toys, caricatures, and political symbolism, is hardly so well adapted to more serious themes. That is not to speak against it, but to assert that, like other methods, it has its limitations. Mr. Carter Preston's work is of very real artistic merit besides being thoroughly original. If he has not created a new art, he has at least developed an old one on very fresh lines.

Certificates in Industrial Design.—It is now over three years since the Board of Education reorganised their system of art examinations, abolished their old tests in separate subjects, and instituted in their stead an examination in industrial design which was so framed as to be suitable only for "those students who take a long and comprehensive course of study with a view to qualifying themselves as highly skilled handicraftsmen or designers for manufactures." The stopping of the old examinations, though hailed with a certain amount of relief in some quarters was on the whole a blow to the teachers who found that they helped to keep up the interest of their students until the late spring and also to the class of students who wanted for some reason or other certificates of proficiency in such subjects as geometrical drawing and freehand—though perhaps the practical usefulness of the examinations was hardly commensurate with the trouble and expense they involved. However that may have been, the new test has not attracted so far a very considerable number of candidates. It appears that the Board have come to see the need of recognising a rather less severe course of study, and are offering under certain very clearly defined conditions to endorse certificates granted by the schools to students who have made a satisfactory number of attendances and passed certain examinations conducted by the institutions concerned. They issued a circular earlier in the

year, and by this time a number of schools have sent in applications to have their certificates recognised next session and are waiting to see what happens. From one point of view there seems very little need for action on the part of the Board as the certificates are clearly not meant for teachers, and employers do not as a rule ask for such things. There is, however, a feeling that a good many students would be more diligent in their studies and more regular in their attendance if they were working for a certificate of an officially recognised standing than they are under present conditions. That being so, it is obviously far better that the certificates should be given on the result of the year's work and not simply and solely on examination results, and that they should be for success in a course and not merely in separate subjects. It is, however, in the eyes of some teachers at any rate, a pity that the provision is only for industrial certificates. The Board, indeed, grants a certificate for elementary school teachers, but it is not only elementary education that has to be taken into account with regard to the supply of art teachers, and whilst it is true that something is nowadays being done for the training of art teachers for secondary schools it can hardly be said that the problem at present has been completely solved. The old art class teacher or art master's certificates were certainly not ideal tests—nor, for the matter of that, were the private certificates with which many teachers in day schools supplemented them—while the question of capacity to teach was not taken into account at all; but there does seem to be room for some sort of certificate rather less advanced than was contemplated in 1911, implying that the holder has had a good all-round grounding in the principles of art with or without the further qualification of being competent to pass on his own knowledge to others. The industrial students as a class are just those who have least need of certificates.

OBITUARY.

LORD GLANTAWE.—The death of Lord Glantawe, who was in his eighty-first year, took place on the 27th inst., after a long illness, at his residence, The Grange, near Swansea.

John Jones Jenkins was born at Clydach, Glamorganshire, in 1835. He began life as a tin-house boy at Upper Forest Works, near Clydach. At a very early age he displayed great business ability, became interested in a number of industries, and was soon regarded as an authority on the Welsh tinplate trade. He also took a leading part in the administrative work of Swansea and district. He was for many years Chairman of the Rhondda and Swansea Bay Railway Company, and guided its fortunes in its struggles with the Great Western Railway Company. He was Chairman and chief proprietor of the Swansea and Mumbles Railway and Pier, and did much to promote the popularity of Mumbles as a health resort. He served as a magistrate and High Sheriff of Glamorganshire, and was three times Mayor of Swansea. During his tenure of this office he had the honour of entertaining King Edward VII. and Queen Alexandra (then Prince and Princess of Wales) on the occasion of the opening of the Prince of Wales Dock, and it was then that he received a knighthood. In 1895 the freedom of Swansea was conferred upon him in recognition of thirty years' public services.

In 1882 Sir John Jenkins was returned to Parliament as Liberal representative for the Carmarthen Boroughs. In 1886 he became a Liberal Unionist, and as such was twice defeated; but in 1895 he regained his former seat and sat in the House of Commons as a Unionist till 1900. He was raised to the peerage in 1906.

Lord Glantawe had been a member of the Royal Society of Arts since 1873.

HENRY ROBERT WARING, M.INST.C.E.—Information has been received of the death of Mr. Henry Robert Waring, which took place in Palma, Majorca, at the age of eighty-two. Nearly the whole of his life was spent in Spain. Originally he was employed in surveying and engineering work in connection with the North of Spain railways, principally about Bilbao and Santander. Whilst he was engaged on this work the Carlist wars broke out and raged with special fury in these parts. Mr. Waring had many narrow escapes from capture, but he finally succeeded in getting away in safety to the east of Spain, and after a few years he obtained the post of managing director of the Majorcan Land Company. This company owned some 8,000 acres of bog land in the island, which, by systematic drainage, has been converted into the most fertile land in Majorca. Mr. Waring retired from active business some twenty-five years ago.

He was elected a member of the Royal Society of Arts in 1907.

DAVID MCHARDY.—Mr. David McHardy died suddenly at his office in Aberdeen on the 23rd inst. at the age of seventy-seven.

He was born in Aberdeen, and educated at the West End Academy, the Grammar School, and the Mechanics' Institute of his native town. He entered his father's works in 1853, and after serving an apprenticeship of six years, and spending three more as a journeyman, he was admitted as a partner. On the retirement of his father twenty years later, he assumed sole control of the business, that of furnishing ironmongers, and under his guidance the firm prospered greatly.

Mr. McHardy was deeply interested in art, particularly as applied to ironwork and kindred subjects. He joined the Royal Society of Arts in 1896, and was also a member of the Aberdeen Philosophical Society. He was also a keen horticulturist and meteorologist, and for many years he served as a Justice of the Peace for the city of Aberdeen.

NOTES ON BOOKS.

THE WORLD'S COTTON CROPS. By John A. Todd, B.L. London: A. & C. Black, Ltd. 10*s.*

The aim of this book, in the author's own words, is "to give, as briefly and comprehensively as possible, an account of the sources of supply of raw cotton in a form sufficiently non-technical to be understood alike by the average grower and consumer, so that the former may learn something of the final destination and use of his crop, and at the same time may know what rivals he has in other countries; while the latter may understand the conditions under which his raw material is produced, and be able to estimate the prospects of the future supply from existing fields, or the possibilities of new sources of supply."

To give some idea of the nature of this task, it may be as well to borrow a few of Professor Todd's statistics. In the year 1902-3 the world's supply of cotton was 17,636,000 bales of 500 lbs. each. Huge as this figure is, it has rapidly risen until in 1913-14 it reached the total of 27,703,000 bales. Nor does the demand show any signs of having approached a final maximum. On the contrary, everything points to its continued and rapid increase. The spread of civilisation, with the consequent demand for more and better clothing, is mentioned as one of the principal factors. "According to a statement attributed to the U.S. Department of Agriculture, it is estimated that of the 1,500,000,000 of the world's population, one half are still only partially clothed, while about 250,000,000 wear practically no clothes at all. Of the clothing actually worn, nine-tenths of the raw material is cotton. The potential demand of the world for raw cotton is therefore almost unlimited."

Besides this, cotton has been found to be a satisfactory substitute for a number of other raw materials. Table and bed "linen," shirts, handkerchiefs, "flannels," tweeds, are largely made of cotton, especially in the Continental ready-made markets; many new uses for it have been discovered lately, *e.g.*, webbing for motor-car tyres, type-writer ribbons, yacht and aeroplane sails, etc.; while most important of all is the great improvement that has been made in the quality of goods that can now be made out of cotton. "Fine white cotton goods, such as nainsooks, madapollams, etc.; fine cotton nets, laces, and curtains; beautifully-finished coloured cotton fabrics, such as dress linings and dress materials of excellent quality and appearance, can now be turned out at prices bringing them within the reach of a class of consumers by whom such goods were a few years ago utterly unattainable."

To supply this enormous demand, immense areas are under cotton in many parts of the world. Professor Todd gives a very interesting account of these various crops. Though he modestly disclaims any pretension to be a botanist or an agriculturist, he has been for years a keen student of economics. He now occupies the chair in that subject at University College, Nottingham, and before he was appointed to this post he spent five years at the Khedivial School of Law in Cairo at a period when, as he truly remarks, economics and cotton were almost synonymous in Egypt. On this account his description of the Egyptian crops is perhaps somewhat more exhaustive than his treatment of some other countries; but he has visited practically the whole of the American cotton belt, and in all cases he has taken the greatest care to have his work revised and checked by first-hand authorities. The result is a highly interesting and valuable book, which will be recognised as a standard work among those engaged in the multifarious branches of cotton industry.

LEVELLING AND ITS GENERAL APPLICATION. Third Edition. By Thomas Holloway. Revised by H. T. Tallack. London. E. & F. N. Spon, Ltd. 2*s.* 6*d.* net.

The first edition of this work appeared in 1886, and was at once welcomed as a handy and practical guide for students of levelling. It has now reached its third edition, for which it has been revised and brought up to date by Mr. H. T. Tallack It gives a clear account of the various instruments used in levelling, and of the numerous problems which a surveyor may expect to meet in carrying out his work. The collection of examination questions at the end of the book will be found useful by students who wish to test their knowledge of the subject.

GENERAL NOTES.

ELECTRICAL MUSEUM.—In response to the appeal which was issued some time ago by the Institution of Electrical Engineers, a number of examples of electrical apparatus of historic interest have from time to time been received. Some of these are now exhibited in the institution, including several early dynamos, an historic series of glow lamps, a collection of supply meters from the earliest types, fuses, and switches; also telegraphic and telephonic apparatus. The collection, though making substantial progress, is still far short of what it should be in order to be thoroughly representative of the early days of the electrical industry. Owing to the many changes, necessitated by the war, that are now taking place in various works, the present is a time when obsolete types of apparatus and early forms of instruments are likely to be thrown out of use, and thus might readily become available. Hence, with the desire of retaining for the benefit of future generations of the profession, objects of historic interest that are still in existence, and which might otherwise be irretrievably lost, the council of the Institution of Electrical Engineers are inviting members and their friends to co-operate by presenting apparatus suitable for the museum. Early forms of electric motors, arc-lamps, and measuring instruments are desired. A Jablochkoff alabaster candle-holder is also wanted.

Persons in possession of suitable objects are invited to send information regarding them to the Secretary of the Institution of Electrical Engineers, Victoria Embankment, W.C., and to state whether they would be prepared to present some or all to the institution, or to deposit them on loan in the museum.

THE NATIONAL PHYSICAL LABORATORY.—The effects of the war are naturally reflected in the Report of the National Physical Laboratory for 1913–14. To begin with, about a quarter of the staff has left for active service. International work of all kinds has practically come to a standstill, while with regard to test work, although the aggregate has sunk, there has been a great increase in certain directions, especially in the departments of electro-technics and optics. One or two recent fires at sea, notably that on the "Volturno" in 1913, have been set down to the presence of barium peroxide in the cargo, and the Board of Trade entrusted the Laboratory with an investigation into the conditions under which this material might take fire; this has resulted in the issue of special instructions for its storage on board ship. The importance of research into the manufacture of optical glass has led the Board of Trade to invite the director to prepare a scheme of research at the Laboratory. Assistance has also been given in a number of ways to the Home Office, the India Office, the Post Office, the Office of Works, and the Crown Agents. An investigation into cracks which have shown themselves in the masonry of the Tower of London promises to be of interest. The statement of work proposed for the year 1915 16 covers an extensive and interesting field.

THE GREAT AQUEDUCT IN APULIA.—The last report of the Italian Minister of Public Works gives some interesting particulars respecting the progress of the great Apulian aqueduct, which, when completed, will furnish a plentiful supply of water for irrigation, motive power, and urban purposes in the region known as the Apulia, in the south of Italy. The main channel, which is 214 kilometres (132 English miles), of which 97 kilometres (50 miles) are tunnel, is now completed. One of the principal branch canals—that in the province of Lecce—is finished, and another in the province of Foggia, 46 kilometres (28 miles) long, is well in hand. Three hundred and twelve kilometres (193 miles) of the channels belonging to the secondary network, of which 19 kilometres (12 miles) are in the province of Foggia, and 268 kilometres (166 miles) in that of Bari, are also finished. Besides this, 48 kilometres (29 miles) of urban conduits for the water supply of numerous small towns and villages in the province of Bari are nearly ready, whilst those in the province of Foggia have just been commenced. Thirty reservoirs in the province of Bari—6 in that of Foggia and 4 in Lecce—are also nearing completion, together with 15 important works for raising water. There still remain no fewer than 1,300 kilometres (about 800 miles) of secondary conduits, in order to complete the network for the distribution of water for agricultural purposes, and 750 kilometres (465 miles) of urban conduits for supplying the various towns and villages with potable water from the River Sele.

IPECACUANHA.—According to a Bulletin issued recently by the Department of Agriculture in the Federated Malay States, the ipecacuanha crop has proved highly profitable in Malaya; but the demand is said to be small, and over-production would result if attempts were made to cultivate it on a large scale. Plants at Kuala Lumpur have done well, but it is stated that they will need great care and attention in order to obtain successful results.

QUEENSLAND MINERAL INDUSTRY.—As was expected under the abnormal circumstances of the year, there was a serious falling-off in mineral production in Queensland in 1914. According to an advance report issued by the Acting Under-Secretary for Mines, the actual value of the total output of minerals was £2,976,280, a decrease of £881,601 as compared with 1913. In addition to the disturbing influence of the war, which may be regarded as the chief cause of such a large decrease, the output was seriously affected by the closing down of the Chillagoe, Great Fitzroy, and Mount Perry works and mines, and, later on, of the Mount Elliott works, as well as by a poor market during a portion of the year for the principal of Queensland's industrial metals. In coal alone was there a satisfactory year, and an increase in production. The gold output showed some slight improvement towards the end of the year, and this has been maintained since its close. It is pointed out in the report that the outlook for the current year indicates that it will at least be better than the preceding period, and may prove very much better.

NEW METHOD OF GROWING CORN.—According to the United States *Experiment Station Record* (Vol. XXXI. No. 7), corn has been planted successfully under dry land conditions in Western Kansas by the following method. The seed is sown in rows twice the usual distance apart, while the plants are twice as thick in the row. The stand is, therefore, the same, but as this method seems to preserve the moisture midway between the rows, the supply is often sufficient to maintain the corn in a flourishing condition during temporary periods of drought, while occasionally it may complete the development of the crop. It is noted that by this method the yields were about thirty bushels per acre, while in adjoining fields, in which the rows were 3½ ft. apart, the yields were only 10 to 12 bushels per acre.

FOTHERGILL LECTURES.

MODERN MUNITIONS OF WAR.

By Professor Vivian B. Lewes, F.I.C., F.C.S.

Lecture I.—Delivered July 7th, 1915.

Guns and Propellants.

The teaching of the first six months of the war was tersely summed up by General French when he said last February: "The problem set is a comparatively simple one—munitions, more munitions, always more munitions," the special munitions meant in this case being the high explosive shells that from the time the war assumed the conditions of a field siege, after the battle of the Aisne, became a necessity for any advance.

When in days to come we review dispassionately the history of the war, and when events have settled down into their proper perspective, we shall see that the wonder of it has been that the supply of munitions has been so good that, in spite of the gigantic dimensions that the war has assumed, our supplies have been kept up far better than in any war of the past, and that any shortage that there has been in any one direction has been due to the entirely new conditions created, which find no parallel in the history of the world.

This phase of the question of munitions will be discussed fully under the subject of the various types of shell, but first it is necessary to make clear the changes in guns and propellants that have brought modern artillery to the paramount position it occupies in this war.

In order to gain an idea of the true proportion of the changes that have occurred, we must carry our minds back to the middle of the last century, when in the Crimea the English and French were struggling as hard to keep the Russians out of Constantinople as they are to-day fighting in the Dardanelles to help them in; and we must contrast the old smooth-bore 68-pounders, using a charge of 16 lb. of black powder, that were the largest guns ashore or afloat at the time of the Crimea, with the 15-in. guns of our super-Dreadnoughts, weighing close on 100 tons, from which a charge of 400 lb. of M. D. cordite hurls a projectile weighing 1,925 lb. with accuracy to a distance of fifteen miles, or with high-angle firing to double that distance.

The changes commenced in the fifties of the last century, when we adopted the idea of rifling ordnance, so as on firing the gun to give the projectile a spin as well as forward velocity. This was found to add to the range and accuracy of fire, and in order to do this satisfactorily the guns had to be increased in length.

The rate at which the size of the big naval guns grew may be gathered from the fact that at the siege of Alexandria in 1882 we had the 80-ton guns of 16-in. calibre, whilst by 1886 we had afloat the 110-ton guns, with a bore of 16·25 in., using a charge of 960 lb. of powder.

Up to this time nothing but gunpowder had been used either as a propellant to drive the projectile from the big guns, or as bursting charges for shells, and the grain used in the smooth-bore 68-pounders was that known as "rifle large grain." It was soon found, however, that the lengthening of the gun caused, with this size of powder, a strain on the breech, and gave but a low muzzle velocity, this being due to the too rapid burning of the powder. Attempts were then made to decrease the rate of combustion by increasing the size of the grain, and with the increase in the size of the guns the powders gradually grew to the large pebble powder, consisting of 1½ inch cubes. Unfortunately the desired effect could not possibly be obtained by alterations of this character, as it is required of a perfect powder that when the charge is fired in the breech of the gun the combustion shall commence comparatively

slowly, so as gradually to overcome the *vis inertiæ* of the projectile without throwing too great a strain on the gun, and shall then increase in rapidity so as to supply gas more and more rapidly to increase the pressure and the momentum of the shot, which should leave the muzzle of the gun with the maximum velocity.

With such forms of powder as cubes or other large grains, however, maximum rapidity of burning and evolution of gas takes place at first, owing to the ignition spreading over the whole surface of the cubes, and instead of the gas coming off with more and more rapidity as the space in the gun became larger, the evolution rapidly diminished with the decrease of surface caused by the burning away of the powder.

In order to avoid this defect as far as possible, built-up charges were resorted to, and it was General Rodman, of the American Service, who first tried to overcome the difficulty by building up the charge of solid slabs perforated with holes, from the interior of which the combustion was started, so as to expose the minimum surface of powder at first, whilst the enlarging holes produced a greater and greater surface of powder to burn and give off gas, as the space behind the projectile increased.

Large perforated cakes, however, are always liable to break, and cannot be made of uniform density, so that it was found far better to mould the powder into hexagonal prisms, with a central core through them, which could be built up into a charge, the prisms being made with such exactitude that when the charge was fired by a layer of fine grain powder at the base of the cartridge, the combustion started from the central cores, and as the powder burnt away a greater and greater surface for combustion was continually formed, until the whole of the charge was spent.

With the continued growth, however, in the size of the guns employed, other changes became necessary, as even when using the black prism powder for built-up charges the pressure given began to throw too severe a strain upon the breech of the gun, even when the cartridges were made up in such a way as to leave air spaces at the seat of the charge, in order to relieve, as far as possible, the initial pressure; and to secure further modifications, alteration in the composition of the powder became necessary, so that by the time the 80- and 100-ton guns were introduced into the Naval Service, prism powder, containing an increased percentage of potassium nitrate and charcoal, with a smaller proportion of sulphur, was in use.

This fitting of the powders to the guns enabled perfect ballistics to be obtained, and really converted the explosive into what Sir Frederick Nathan was fond of calling these powders—"propellants."

These powders had one characteristic, however, in common with the old grain powder, and that was that they gave volumes of smoke; and when rapid-firing guns were introduced, so dense was the cloud produced, that after the first few rounds nothing could be seen, and the guns became useless until the smoke had cleared. This rendered a smokeless powder a necessity, and the history of the inception of the smokeless powders of to-day is full of interest.

In any successful explosive certain conditions have to be fulfilled: one must be able to concentrate in a small space bodies which will act upon each other independently of the air with enormous rapidity, forming the largest possible volumes of gas, which, expanded by the heat of the action and having to find a way for itself, gives the explosive effect. If this change takes an appreciable time, the body can be used as a "propellant" in a gun, and gunpowder is of this character. When, however, the change takes place practically instantaneously, it cannot be used in a gun, and is used in high explosive shells, bombs, torpedoes, and mines, and such bodies we call "high explosives," nitroglycerin being an example of this class.

When during the formation of the gas from the solid in explosion other solid compounds are formed as well, these solids are blown out in a fused form as fine particles, and form a cloud—smoke; but if only gases are produced the explosion is smokeless. Gunpowder, on being fired, gives nearly half its weight as solids, and therefore forms clouds of smoke; guncotton is resolved entirely into gases and gives no smoke.

When the necessity for a smokeless powder became urgent, it was naturally to nitrocotton that attention was most largely turned; but all attempts to convert it from an "explosive" to a "propellant" failed, until it was found by Mr. Walter Reid that its rate of combustion could be slowed down sufficiently to make an excellent propellant by destroying the original cotton structure that still existed in the nitrocotton by gelatinising it with alcohol and ether. If cotton fibre is examined under the microscope

it is found to consist of very minute tubes, and in the process of converting the cotton into "guncotton"—by soaking it in a mixture of the strongest nitric and sulphuric acids, washing out all acid and drying—this structure remains. If the guncotton were used as a charge in a big gun, no matter how much it was compressed, the flame of the combustion would be pressed back into these tubes, and so accelerate the burning as to give almost instantaneous explosion, straining the gun and giving very low velocity to the projectile.

Nitroglycerin is an even more rapid "explosive" than guncotton, and if used in a gun would burst it, probably without driving out the projectile at all. Nobel, however, in 1875 discovered that if a low form of guncotton was macerated in nitroglycerin, the guncotton was gelatinised, all structure disappeared, and both explosives became so tamed in their action that they were converted into a perfect blasting explosive, and in 1888 the mixture was made the basis of a smokeless propellant far superior to gunpowder. This idea was improved upon by Sir Frederick Abel and Sir James Dewar, who found that the highest form of guncotton, which is unacted upon by nitroglycerin, could be got into a gelatinised mass with nitroglycerin if a common solvent, such as acetone, was used to blend them, and afterwards evaporated out; and this blend, with 5 per cent. of vaselin to increase the stability and lubricate the gun, forms our modern "propellant" cordite, so named from the fact that it is cast into sticks, rods or cords, according to the size of the gun in which it is to be used.

The "Mark I" cordite first made contained 68 per cent. of nitroglycerin, and the heat of its combustion in the guns gave rise to a troublesome form of erosion, which in the South African War shortened the lives of the field guns, so that they had to be relined after a certain number of rounds had been fired. This led to an alteration in the proportion of the ingredients in the M. D. cordite now used in all arms, from the 15-in. guns of our super-Dreadnoughts to the Service rifles.

Our allies and enemies alike use smokeless powders of a somewhat different type, made by gelatinising nitrocotton without any nitroglycerin, for their field artillery and rifles; but in the German and Austrian naval guns nitroglycerin powders of much the same kind as our "cordite" are used, as a larger charge of nitrocotton powder has to be employed than of a nitroglycerin powder, and this means larger chambers in the guns and larger magazines to carry the necessary amount of explosive.

As may be imagined, the introduction of smokeless powders made an immediate change in gun construction, as much smaller chambers were needed, and the possibility of throwing the pressures further forward in the gun enabled guns to be made lighter. As a result our biggest naval guns are only 15 in., as against the 16·25-in. 110-ton guns in use in 1886, and the charge of M. D. cordite only 400 lb., as against the 960 lb. of prism powder, but the muzzle velocity has increased by nearly 50 per cent., whilst the projectile is far heavier.

Our enemies in the field are using guns, howitzers, and mortars, the two latter classes being used for indirect fire from behind shelter, for which their high trajectory specially fits them, whilst the field artillery used by them consists chiefly of quick-firing 77 millimetre guns (3·03-in.). One of the new features they have introduced into the present warfare is the use of siege guns of much larger size, transported by motors, and so made available for field work, whilst amongst the other artillery in use are the celebrated Krupp siege howitzers of 16·8-in. calibre; but probably the most deadly innovation has been the almost unlimited use of machine guns, to the manufacture of which the Germans have devoted many years, and of which they have an enormous supply.

Lecture II.—Delivered July 14th, 1915.

SHELLS AND HIGH EXPLOSIVES.

In the last lecture the propellants used in the guns during the present war were dealt with, and it was seen that although for field artillery and rifles our allies and enemies were both using nitrocotton powders, yet in nearly every case, for naval warfare, owing to restricted magazine space, nitroglycerin powders of the character of our Service propellant "cordite" were employed, as a smaller charge is needed to obtain the same muzzle velocity. For instance, with the German 15-in. gun, to give a muzzle velocity of 3,000 foot-seconds, the charge of nitrocotton that has to be employed is 695 lb., whilst with one of our own 15-in. guns a charge of only 400 lb. is employed.

Ever since war was declared the explosive factories all over England have been working in unison and have kept up an ample supply of propellants, whilst in nearly every works extensions are being erected, which in early autumn will yield an almost inexhaustible quantity.

The shells used in big guns and field artillery may be divided into two main classes: shrapnel, which is utilised against troops in the field and which is of but little use against fortifications or trenches, and high explosive shells, which may be either armour-piercing or ordinary.

The shrapnel shell is a hollow, cylindrical steel projectile, packed with bullets, at the base of which is a bursting charge that may be gunpowder or high explosive, whilst in the nose of the shell is arranged the time fuse, connected by a tube to the bursting charge. This can be so regulated that the shell explodes in the air at any desired point, the bullets and fragments of the shell being driven forward and spreading over a considerable area. The shrapnel used in the ordinary field gun is an 18-lb. projectile, containing 375 bullets, and when burst at the right altitude is a most deadly weapon against troops, especially when in massed formation, and ever since its invention by the officer whose name it bears it has been looked upon in the Services as the form of shell most necessary in field operations. During the present war our supplies have been ample for all requirements.

For fortified trench warfare, such as has been the characteristic feature of the fighting on the western front since September, shrapnel is not effective, as it does but little damage to earthworks, wire entanglements, and other defences, and this practically new phase of field warfare has to be met by the use of high explosive shells, capable of detonating with such enormous concussive power as to destroy physical obstructions, crumble earthworks, clear wire entanglements, and reduce the defenders in the trenches to a dazed and stunned condition by the action of concussion on the heart and nerves.

Under the conditions created in the present war both classes of shells are needed in the field—the shrapnel to resist infantry attack, the high explosive shells to clear the ground and prepare the way for attack on the enemy, and it has been an insufficiency in the supply of the latter which has given rise to so much criticism, mostly undeserved and wholly unwise. At the present time obstacles to supply in all directions have been surmounted, and a steady and increasing stream of shell is flowing to the front.

The high explosive shell is made of forged steel with comparatively thin walls and a heavy bursting charge, but the large naval shells and those for the siege guns, which have to penetrate heavy armour, are made from ingots of chrome or chrome-nickel steel, forged, hardened, with the nose capped with soft steel, which prevents the shell from shattering on impact with the hardened steel armour. These shells also contain a heavy charge of high explosive, generally cast into the shell in a fused condition.

All these forms of shell are fitted with the usual soft copper driving bands near the base of the shells. These bands take the place of the projections used in the early forms of shell to fit the rifling of the gun. The copper band under the pressure existing during the firing of the charge is pressed into the grooves of the rifling in the gun, not only imparting rotation to the projectile, but also acting as a gas check to prevent the rush of the gas past the projectile, an action which had accentuated the serious erosion with the Mark I cordite.

For trench fighting the grenade has now again come into use, and the most modern forms are in reality miniature shrapnel shells, which are fitted on to a rod that can be fired from a rifle, or, where the trenches are close together, can be thrown or slung by hand. The body of the grenade is made of steel or malleable iron, so serrated as to break up on explosion into many pieces. It contains a charge of a T.N.T. explosive, and a tetryl detonator fired on impact by a needle liberated only after the grenade has travelled a certain distance, so as to render premature explosion impossible. The weight of such a grenade is about 23 oz., and when fired its range would be about 300 yards, but when hand-thrown not more than 40 or 50. Its flight through the air is steadied when fired by the rod, which for hand use is replaced by a rope tail.

The difference between a "propellant" and a "high explosive" is entirely one of rapidity in explosion. In both cases they are bodies containing in a small space combustible material that can be burnt to form enormous volumes of gaseous products, together with oxygen-bearing radicals capable of carrying on the combustion with great rapidity independently of the exterior air. We have seen that there was in gunpowder carbon in the form of charcoal, mixed with sulphur and potassium nitrate, the latter being the oxygen-carrying body, and on the powder being ignited a chemical action took place, which liberated an amount of gas many hundred times the original volume of the powder. This conversion took a measurable time for its completion, and a "propellant" was the result. On the other

hand, when cotton is treated with the strongest nitric acid mixed with sulphuric acid, the cotton fibre becomes nitrated, and a molecule is produced in which there are present the hydrogen and carbon of the cellulose, together with oxygen held in combination by the inert nitrogen of the nitrate radical. On such a compound being ignited it burns, as we saw in the case of guncotton, with considerable rapidity; but in a gun the rate of combustion is often accelerated, and a still more rapid form of explosion takes place.

It was in 1868 that one of Sir Frederick Abel's assistants, Mr. E. O. Brown, discovered that when a mercuric fulminate cap was exploded in contact with compressed guncotton the unconfined mass exploded with enormous violence, and that whereas an ordinary train of guncotton would take several seconds to burn a few feet, yet if compressed guncotton were detonated the explosion travels at the rate of 200 miles a minute, and as there is no time for the displacement of the air, the enormous volume of gas created having to find room for itself gives as great a destructive effect as if the guncotton had been tamped into a bore-hole in the object to be destroyed. Bodies which are capable of this accelerated form of explosion are said to be "high explosives," and unless the tendency to detonate can be overcome, as in the making of cordite from nitroglycerin and nitrocotton, they cannot be used as propellants, as there would be no time to overcome the *vis inertiæ* of the projectile and the gun would be either strained or burst.

Nitroglycerin is a very good example of a high explosive, but practically is of no use in Service work outside the manufacture of cordite, as it is far too dangerous to handle, and if used in a shell would be liable to premature explosion. It must always be remembered that science could provide explosives more powerful than those in Service use were it not quite as important to ensure safety for those using the explosive as to obtain destructive effects on the enemy.

With most of these high explosives the explosion gives rise to its greatest effects in a downward direction, which may be explained by the fact that the decomposition is so enormously rapid that there is no time to displace the atmosphere, and the recoil from the attempt to push up an elastic medium like air causes the smashing down of rigid bodies below the seat of the explosion.

One of the things that strikes the ordinary observer most when considering the composition of the explosives of to-day is that they are all derived from substances of the most commonplace and harmless description. We have seen that cotton and glycerin when nitrated and blended with vaselin yield cordite, which serves as a propellant in all our guns, whilst the high explosives used in shells, torpedo heads, mines, and aviators' bombs, are almost entirely derived from coal tar derivatives by nitration.

When coal tar is subjected to fractional distillation the portion which comes over up to a temperature of 150° C. is called "light oil," and contains all the compounds of low boiling-point found in the tar, and, as we shall see, from this several of our most valuable explosives can be obtained. When these light oils have distilled over, the next fraction or "middle oil" yields phenol or carbolic acid, a body which when nitrated gives picric acid, the basis of the French high explosive melinite, the Japanese shimose powder, and the English lyddite.

In the manufacture of picric acid the fraction coming over on the distillation of the tar between 150° and 200° C., after the naphthalene has been allowed to settle out on standing, is agitated with a solution of caustic soda, which forms sodium phenolate with the carbolic acid. This sinks to the bottom of the vessel and is drawn off and treated with sulphuric acid, whereby the carbolic acid is set free. The acid mixture is fractionally distilled, and the phenol comes over between 180° and 190° C., crystallising from the distillate in needle-shaped crystals.

Phenol or carbolic acid when pure fuses at 42° C. and boils at 182° C.

The phenol is mixed with an equal weight of concentrated sulphuric acid, and heated in an iron vessel to a little over 100° C. When cold the mixture is dissolved in twice its weight of water, and added gradually to three times its weight of strong nitric acid, precautions being taken to prevent undue rise of temperature; when fuming has ceased steam-heat is employed to complete the nitrification. On cooling, crystals of picric acid separate out and can be purified by recrystallisation.

Picric acid is a nitro-substitution product, three atoms of the hydrogen in the original phenol being replaced by the radical nitryl, and it forms with metals a class of salts called "picrates." The potassium salt was suggested as a bursting charge for shells nearly fifty years ago, whilst Sprengel showed it could be detonated, and, later, Turpin employed the acid itself as an explosive. It was found

possible to get a great weight of explosive into a small space, as the acid could be melted and poured into the shell in a molten condition. Picric acid *per se* is a very safe explosive, but has the drawback of acting on metals to form picrates, some of which are far more sensitive to disturbing influences than the acid itself.

Experiences with lyddite shells in the South African War showed their behaviour to be very erratic, some exploding with great effect whilst others gave disappointing results. This was due to the fact that picric acid requires a powerful detonator for obtaining the highest explosive effect, and the use of such a detonator was dangerous and might cause a premature explosion of the shell within the gun.

The disadvantages inherent in the use of picric acid led to attempts being made to replace it by some other material of the same character, which could be used as a high explosive in a bursting charge and yet be free from these drawbacks. Such a body has been found in trinitrotoluol, and although its explosive force is slightly less than that of picric acid, the pressure of the latter being 135,820 lb. on the square inch as against 119,000 for trinitrotoluol, yet its advantages more than compensate for this difference. Not being of an acid nature, trinitrotoluol, or T.N.T. as it is termed, cannot accidentally form more sensitive salts, it is without action on metals, and is perfectly stable.

Trinitrotoluol is obtained by the nitration of toluene, which is contained in the crude benzol distilled from coal tar and washed out from coal gas, and forms one of the group of so-called aromatic hydrocarbons. The crude benzol contains roughly—

Benzene	50 per cent.
Toluene	36 ,,
Xylene	11 ,,
Other bodies	3 ,,

The toluene is obtained by careful fractionation of the crude benzol, the boiling-point being intermediate between those of benzene and xylene—

	Specific gravity.	Boiling-point.
Benzene	0·886	80·5
Toluene	0·869	110·0
Xylene .	about 0·87	137 – 140

When coal is distilled at the lowest possible temperature the tar is fairly light as regards specific gravity and of an oily character, is rich in paraffin hydrocarbons, and contains but few aromatic hydrocarbons. The distillation of a ton of coal yields about 20 gallons of such tar, the constituents of which are even of greater value than those of the high-temperature tar made in the gasworks and coke ovens of the Empire. On now raising the temperature of distillation of the coal to about that which used to be employed in the days of the old iron coal-gas retorts, a volume of coal gas, amounting to about 9,000 cubic feet, is yielded, the coke is harder in quality, and the tar shrinks from about 20 gallons to about 16 gallons to the ton. Tar made at this temperature contains a much higher proportion of aromatic hydro-carbons than that made at the lower temperature, and it is possible to obtain nearly a gallon of toluene per ton of coal distilled by recovery from both the tar and gas.

At the temperature used in practice at the present time for the manufacture of both coal gas and metallurgical coke, which is as high as the materials of which the retorts and ovens are constructed will stand, the aromatic hydrocarbons are largely destroyed or converted into naphthalene, and a third of a gallon of toluene is all that can be obtained from the tar and gas yielded by a ton of coal.

Toluene, to be used for the manufacture of trinitrotoluene, should be a clear water-white liquid, free from any suspended solid matter, and having a specific gravity of not less than 0·868 or more than 0·870 at 15·5° C. Its boiling-point must approximate closely to 110° C., and 90 cc. shaken with 10 cc. of 90 per cent. sulphuric acid for five minutes should give only a slight colour in the acid layer after settling.

The preparation of trinitrotoluene is carried out in three distinct stages, the toluene being converted first into the mono-nitro compound, which is then further treated with nitric acid at a slightly increased temperature to convert it into the dinitrotoluene, this being finally nitrated in sulphuric acid solution with strong nitric acid to trinitrotoluene.

On a large scale, trinitrotoluene is manufactured commercially from the orthonitrotoluene by a sulphonating process of the same character as that used in the manufacture of picric acid, and the crude crystals obtained in the final nitration are purified by solution in alcohol, filtration, and recrystallisation, the crystals being freed from alcohol in a centrifugal machine and air-dried.

Trinitrotoluene when pure has no odour and is a yellowish crystalline powder, which darkens slightly on keeping and has a melting-point of 81·5° C.; the presence in it, however, of isomers

lowers its melting-point to 79° C. It is perfectly stable and unaffected by contact with metals, forming no compounds with them even in the presence of moisture. It cannot be exploded by flame or strong percussion, and a rifle bullet may be fired through it without any effect on the mass. When heated to 180° C. it ignites and burns with a heavy black smoke; but when detonated by a mercuric fulminate detonator the explosion is of great violence, and gives the heavy black smoke which has been such a characteristic of the high explosive shells used in the present war. Even when detonated under water, as has been the case on several occasions with bombs aimed by aviators at vessels, a column of black smoke is thrown up above the surface of the water.

The formation of these volumes of black smoke on detonation of the T.N.T. has given rise to the names given to shells containing this explosive of "Black Marias," "Coal boxes," and "Jack Johnsons," and the fact that this cloud of carbonaceous matter is produced shows conclusively that the oxygen contained in the nitryl radical present in the explosive is insufficient for its complete combustion. An excellent explosive used during the Balkan War, and now largely employed by the Austrians and Russians, is known as ammonal, in which 12 to 15 per cent. of T.N.T. is mixed with an oxidising compound, ammonium nitrate, a little aluminium powder, and a trace of charcoal. This mixture gives even better results than the T.N.T. alone, and its only drawback is the hygroscopic character of the ammonium nitrate, which necessitates the material being made up in air-tight cartridges. It forms, however, a most effective bursting charge, and although the rate of detonation of the trinitrotoluene is reduced by the admixture of the oxidising compounds, the shattering effect is even more destructive than when the explosive is used alone, as the pieces of shell scattered are larger in size.

An improved form of this explosive is being made on a large scale in England for use by the Allies, and renders the supply of high explosives for shells perfectly adequate.

Toluene is also being produced synthetically from other hydrocarbons by the action of heat and pressure, and it is safe to say that any requirements for toluene to nitrate can be amply met.

Under the influence of nitration other constituents of tar are converted into effective explosives, dinitrobenzol being the basis of such mining explosives as "Roburite" and "Bellite," whilst trinitrocresol has been used largely in place of picric acid under the name of "Ecrasite," but it shares with picric acid the drawbacks of forming more sensitive compounds with bases, and of having an acid reaction.

Expert opinion has by no means settled which is really the best of the high explosives, and although it was the Germans who were chiefly responsible for bringing T.N.T. into such prominence, there are not wanting signs that they are largely reverting to picric acid.

Probably the most powerful explosive known is made from benzene by converting it into anilin, and by nitration making this into tetranito-anilin, an explosive of which a great deal more will be heard, whilst another derivative, tetranitromethylanilin, known as "tetryl," is being used largely for detonators in place of mercuric fulminate.

It has already been mentioned that the great value of the high explosive is the terrible concussion transmitted through the air by the detonation, which numbs, and often kills, the defenders in the trenches without their being struck.

The effect of the concussion frequently shows itself by loss of memory, by nervous breakdown, and by heart trouble, many cases occurring in which men have been disabled without been killed, and have afterwards been found to be suffering from serious displacement of the heart. In the early stages of the war the fact that men were killed without being wounded gave rise to wild rumours of intensely poisonous shells, so fatal in their results that men and animals were found in the exact positions in which death had overtaken them. One ingenious correspondent christened this explosive "Turpinite," and devoted a long article to the effects produced, which made it clear to anyone with knowledge of the subject that concussion, and not poison, could have been the only explanation of the deaths produced by it.

Lecture III.—Delivered July 21st, 1915.

Poison Gases and Incendiary Bombs.

The use of asphyxiating gas in warfare, as long as the effect was merely to drive men from the trenches, to produce coma, or inflict death without excessive suffering, would be but little more horrible than the legitimate methods of fighting; but the use of gases which, if they

fail in the intended effect, produce results accentuated by intense suffering and life-long lung trouble is indefensible.

There are many gases known which are irrespirable. Some, like carbon dioxide, nitrogen and hydrogen, act merely in the same way as water would do by cutting off the oxygen supply to the lungs, but have no toxic action on the system. Other gases, like carbon monoxide and cyanogen, are powerful poisons, less than 1 per cent. of which in the air will cause death by purely toxic action. Others, again, like sulphur dioxide, chlorine and bromine, may act by producing spasms of the glottis and subsequent asphyxiation.

The use of asphyxiating gas is by no means the simple problem that one might imagine. In the first place, gases differ from other forms of matter in that the molecules of which they consist being free from cohesion are able to intermingle no matter how different may be their weights. This process is known as "diffusion," and unless the gas is very considerably heavier than air it intermingles with the atmosphere so quickly as to prevent it spreading in a poisonous quantity over any considerable area. No gas which was not more than double the weight of air could be used effectively to carry in sufficient quantity to be poisonous at the distances likely to exist between the trenches.

The weight of a gas is represented by its density, that is, how many times it is heavier than hydrogen, the lightest gas known. In the following table are shown the densities of the various gases suspected of having been used or possible to use and the relation of their weight to an equal volume of air :—

	Density	Times heavier than air.
Sulphur dioxide .	32	2·21
Nitrogen tetroxide .	46	3·17
Chlorine. . . .	35·5	2·45
Bromine vapour .	80	5·53
Phosgene . . .	50·6	3·49

By the laws of diffusion, gases intermingle at a rate which is inversely proportional to the square roots of their densities, but air currents or wind enormously increase the rate of admixture, so that with anything like a breeze blowing it would be impossible to use them successfully, whilst the opportunity for "frightfulness" is of course limited by the direction of the wind, so that in Flanders it is only with the wind in the north, or a point or two either side, that effective use could be made of them.

During the past few months the prevailing winds have been in the enemy's favour for considerably more than the normal period, and it is to be hoped that during the next few months, with the prevalent wind from the south or south-west, the opportunity of using these gases will be reduced to a minimum.

A proof of the wonderful power of diffusion in so rapidly causing the mixing of poisonous gases with the air as to render them practically harmless is to be found in the case of carbon monoxide, a gas so poisonous that 1 per cent. proves fatal. All the propellants now in use give enormous volumes of this gas amongst their products of combustion; M.D. cordite gives on firing 50 per cent. of the permanent gases produced as carbon monoxide, or 40 per cent. including the water vapour. One of the 15-in. guns on a super-Dreadnought, with its charge of 400 lb. of cordite, gives about 2,500 cubic feet of this gas each time the big gun is fired, and in every battle fought since the commencement of the war thousands of cubic feet of this gas have been produced, yet not one case of death from poisoning by it can be traced.

The reason of this is that even when cooled down to air temperature it is a trace lighter than air and diffuses so rapidly that enough is never present to prove fatal. The same applies to cyanogen, which also is lighter than air, and these two true poison gases would be useless as factors in a gas attack where the asphyxiant has to travel some little distance.

Taking now the properties of the gases which from their weight it is possible to use, we find that sulphur dioxide is a clear colourless gas, with that intensely penetrating odour which is evolved when sulphur in any of its forms is burnt in air, and which has attracted attention to it from the earliest times. The preparation of the gas is exceedingly simple, as all that is necessary to produce it is to throw finely-powdered sulphur on to an open fire, when combination between the sulphur and oxygen of the air takes place with a blue lambent flame, and the gas pours off with its choking odour. This gas can be reduced to a liquid either by the cold given by a freezing mixture of ice and salt, or by a pressure of three atmospheres, and in the liquid state can be stored in any vessel capable of withstanding pressure, with the result that liquid sulphur dioxide can be bought in siphons of very much the same character as those used for containing soda water.

The power of liquefying a gas by cold, pressure, or a combination of the two, leads to

the possibility of getting into an extremely convenient form large quantities of these asphyxiating gases, all of those enumerated being capable of easy liquefaction; but on again allowing these liquids to assume the gaseous form the trouble arises that heat is absorbed during the change of state, and that in many cases the volatilising liquid has so much heat withdrawn from it as to be frozen into a solid, the flow of gas being stopped or so retarded as to be rendered useless. For this reason the liquid must be discharged either into a vaporising chamber of such size that the sides cannot be cooled down to a point likely to interfere with the escape, or else into a heated coil or tube which will prevent the action of the intense cold.

Chlorine, which is in all probability the gas which has been used to the greatest extent, is of a yellowish green colour. It can be liquefied under a pressure of 6 atmospheres, and has an insupportable odour. When inhaled even in minute quantities it causes choking, and air containing 2 per cent. of it rapidly proves fatal. This gas may be made with the greatest ease by heating a mixture of hydrochloric acid and black oxide of manganese, but it is now produced in large quantities in certain electrolytic processes, from which it can be collected and liquefied, the liquid being stored in lead-lined steel cylinders closed by a valve.

In such a cylinder the gas above the liquid exercises a pressure of at least 90 lb. on the square inch, so that if a cylinder containing it be fitted with a tube which passes down into the liquid and is provided at its exit from the cylinder with a valve, on opening the valve the liquid is blown out in the form of a spray which at atmospheric pressure instantly assumes the gaseous form, and it is in this way that it has been chiefly used. It is reported, however, that where the German trenches are of a more or less permanent character, broad tubes with valves at intervals are laid a few feet in front of the trenches with the openings pointed towards the Allies, the trunk tubes being connected with a gasholder and chlorine plant situated in some sheltered spot some little distance away, so that the mere opening of the valve sets free a flood of gas without the disturbing influence of the cooling effect produced when gas is liberated from a cylinder of compressed liquid. The yellow colour of the gas employed has been a marked feature of all the more serious gas attacks, but it must be remembered that either chlorine or nitrogen tetroxide would give very much this effect, although the latter would be browner in colour.

There are five oxides of nitrogen—nitrogen monoxide, the nitrous oxide of the dentist, or laughing gas as it used to be called. This would never be used as it is not an asphyxiant, and in the diluted condition in which it would reach the trenches would at most give rise to a pleasant feeling of slight intoxication. The fifth oxide of nitrogen—nitrogen pentoxide—is a solid. When the other gaseous oxides of nitrogen are employed for asphyxiation, no matter what the oxide liberated, by the time it had reached the opposite trench it would be nitrogen tetroxide, as nitrogen dioxide and nitrogen trioxide both take up oxygen from the air and become converted into the tetroxide.

Nitrogen tetroxide constitutes the fumes formed during the action of nitric acid on various substances in contact with air, and can be liquefied at temperatures below 26 C. to a liquid varying in colour with the temperature. Most observers from the front insist that this gas has been largely used; but its very general adoption seems doubtful, as nitric acid and the oxides of nitrogen play so important a part in the manufacture of explosives that, in spite of the large quantities of nitric acid made by electrical processes from atmospheric nitrogen, the enemy cannot spare much for this purpose, more especially as chlorine is more effective and can be obtained in any desired quantity without affecting the supply of any other munitions of war.

Only two liquid elements are known, mercury and bromine, and the latter, which is closely akin to chlorine in all its properties, becomes a vapour at atmospheric temperatures, and boils at 59° C. Germany produces practically the whole European supply from traces of magnesium bromide found in the great salt mines at Stassfurth. It is a reddish-brown liquid and gives a vapour of the same colour: its effect upon the system is the same as that of chlorine, and it is supposed to have been used by the Germans in asphyxiating shells, the bursting of which would scatter the liquid bromine and facilitate its conversion into vapour, which, owing to its great weight, would sink to the ground.

It seems possible that sulphur dioxide and chlorine have been the chief asphyxiants used, and many have been the proposals made to fight the use of these gases and render the attacks as little harmful as possible. It would take a series of lectures to consider these, and

it must be remembered that only the simplest measures are available in action. We all know the difficulty of getting men in chemical works to wear respirators, and it is very much the same in action; and, after all is said and done, a cloth well wetted with a solution of washing soda, tied over the mouth and nose when a gas attack is developing, affords excellent protection, whilst the respirators now supplied to the troops have proved effective.

Of the proposals to prevent the gas reaching the trenches, such suggestions as neutralising the gases by ammonia fumes are not practicable, as the air current is setting on to the trenches, or there would be no danger from the enemy's gas, and ammonia gas liberated close in front of our own trenches would probably choke as many as the enemy's gas would have done.

A suggestion, however, that might be both practical and efficient is to have in the trench long iron troughs of about the section of a gutter pipe, which, when a gas attack was developing, could be filled with sawdust saturated with petrol and ignited. Wires attached to each end of the trough and passing over a pulley block fixed to a stump at the first entanglements, would enable the fiercely burning mass to be pulled out ten or twelve feet in front of the trench. The strong up-current caused by the burning mass would throw most of the smoke and poison gas over the trench, and if the troughs were six feet apart, the defenders in the trenches could see through the gaps if any rush of the enemy was starting.

The question of whether England should retaliate in kind is a very open one. The element of surprise is needed to make gas attacks successful, and inasmuch as we have not the remotest chance of surprising the Germans, who expect and are prepared for retaliation, it is far better to keep our hands clean, and fight the same straight fight that has always pulled us through.

A form of poisoning used by the enemy has been the employment of amorphous phosphorus in the shells used partly for the marking of ranges. Amorphous phosphorus is a violet-brown powder, largely used in the composition on safety match-boxes, and differs widely from yellow phosphorus in that it is non-poisonous and inflammable only at a temperature that converts it into the inflammable yellow form. A small cartridge of this included in the 18-pounder shells used for range-marking is converted by the heat of explosion into the ordinary variety, which burns giving a dense white fume of phosphorous pentoxide. This marks the position of the bursting shell by day and earns for these shells the name of "woolly bears," while a flame performs the same function by night. When, however, a fragment of such a shell inflicts a wound, the phosphorus poisons it and complications ensue.

Probably the phase of "frightfulness" that interests the British public as much as any are the bombs dropped by aeroplanes and Zeppelins, of which several distinct varieties are in use.

The British Air Service during this war have used the "Marten Hale bombs," and the execution they have wrought in their numerous and brilliant raids speaks well for the construction of these deadly instruments. They are made in two sizes. The small bomb, fully loaded, weighs 10 lb., and the larger one 20 lb. The latter is the one most in favour with the Air Service, and as many of them as fifteen can be carried on the ordinary aeroplane. The 20-lb. bomb has a high explosive bursting charge of trinitrotoluol, in addition to which there is the primer, consisting of tetryl.

The structural damage done by this large amount of explosive is very great, in addition to which the bomb itself is fragmented into about a thousand pieces, all of which have deadly shrapnel effect.

Amongst the raids two stand out very prominently: firstly, the Düsseldorf event, the official record of which shows that one of the latest Zeppelins was totally destroyed, as also at the same time the huge shed in which it was housed, the machinery hall adjoining and the gas-producing plant, the total damage being estimated at something like £375,000; and secondly, and more recently, the daring exploit of the late Lieutenant Warneford, who, after dropping five bombs and missing his mark, hit the target with the sixth, bringing down one of the huge Zeppelin airships in mid-air, causing its complete destruction and death to every member of the crew, whilst the aviator most miraculously escaped with his own life; but most unhappily met with an accidental death a few days later during a peaceful flight in Paris.

The feature in this design of bomb which has recommended it to our authorities is the extreme safety with which it may be handled, transported, and employed. Normally, the detonator is contained within the tailpiece at such a distance from the main bursting charge that it cannot detonate the latter should the bombs carried by the aviator be hit by anti-aircraft shells; or should he come to the ground

with any violence the greatest result would be a small local fragmentation of the tail part in which the detonator is located. The bomb, to become armed, actually requires to travel a distance of 200 ft. through the air, during which the four small vanes at the top make four and a half revolutions, whereby the detonator is released from a retaining spindle, and is then free immediately on impact or retardation to fly forward into the body of the bursting charge, where it impinges on a firing needle and immediately creates the principal explosion.

These bombs are carried and dropped from the aeroplane in a horizontal position. The three large lower vanes are fixtures, their function being to bring the bomb as quickly as possible into a perpendicular position, and to give it a straight course during its downward flight. These vanes accomplish this remarkably quickly, and although the bomb when launched assumes a pendulum action, it recovers almost directly and becomes perfectly straight in its flight after having travelled about 150 ft.

The bombs are of two types, shrapnel and high explosive: the former carries an explosive charge of 4 lb. 2¼ oz. of trinitrotoluene and 321 steel balls, which, with the fragments of the shell, will often give over a thousand pieces propelled on bursting with enormous force; the latter type, designed for dropping on warships and fortified positions where structural damage is the important effect, carries an explosive charge of 6 lb. 3¼ oz. of T.N.T.

Besides these, incendiary bombs are used which differ somewhat from those used by the enemy, and which, for manifest reasons, cannot be discussed. The incendiary bombs used by the Germans, two forms of which are exhibited, consist of an outer skin wound round with tarred rope, forming a chamber filled with resin, celluloid cuttings, etc., in the centre of which is a charge composed of a mixture of very finely-divided aluminium and oxide of iron. This, when ignited, develops an enormous amount of heat, owing to the combination of the oxygen of the oxide of iron with the aluminium.

This mixture is known in trade as "Thermit"; it was successfully introduced for practical use by Goldschmidt in 1898, and is now largely used for welding rails and other iron and steel structures, and also repairing castings; indeed, for any purpose for which intense local heating is required. In many of these bombs there is a layer of amorphous phosphorus at the base, which, converted into phosphorus vapour by the heat of the thermit reaction, burns with a rush of poisonous flame, igniting everything around, and giving burns which, if not fatal, are poisoned and difficult to heal. It also produces a cloud of fumes of phosphorous pentoxide.

As with the poison gas, the best means of dealing with the danger is the simplest. A few buckets of water applied at once are far better than the most expensive forms of apparatus; and should you have the misfortune to receive one of these Heaven-sent messengers on your premises, the rules laid down by the Fire Prevention Committee are the best that can be devised.

INDUSTRIAL DEVELOPMENT IN THE UNITED PROVINCES.

The report, recently issued, of the committee appointed to inquire into the possibilities of industrial development in the United Provinces—and in particular in those branches of trade hitherto largely monopolised by Germany and Austria—is of an eminently practical character. The committee did not content themselves with pointing out possible lines of development, but, as their report shows, were in some instances able to secure substantial assistance to new or struggling industries. Meetings were held at the principal trading centres of the provinces and questions relating to trade development discussed with those interested. In some cases existing trades were found to be hampered by difficulty in procuring materials, and a good deal of the time of the committee is stated to have been taken up in meeting those requirements. An interesting account is given of the attempts made to foster the production of two chemical substances in considerable request—oxide of cobalt and bichromate of potash—the raw material for which is procurable in India, and the committee believe that with certain concessions from Government in the way of freight an indigenous industry in this connection can be started. The principal industries dealt with were glass bangles, hosiery, wool, lamp-making, dyeing, and calico printing, crushing of oil-seeds, alkalines, and chemicals. These industries already exist in the provinces in various stages of development, and the recommendations made are the result of inquiry and discussion with traders as to the best way in which they can be encouraged. The recommendations necessarily differ with the individual industry. In some cases, as in the glass and lamp trade, the employment of experts was recommended; in others, such as alkalines and chemicals, a removal of certain restrictions and the grant of concessions was suggested. Information was procured in other instances as to the cost of installing the necessary machinery and starting the industry. Throughout it is evident that the creation of the post of

Director of Industries and the appointment of an expert staff and trained instructors of technical schools has greatly facilitated an inquiry of this nature, and rendered it possible to give assistance of a special nature. The report contains an appendix by the assistant chemist deputed to inquire into the procuring of vegetable dyes until a sufficient quantity of artificial dyeing material is again on the market. The same officer is also stated to be working on the improvement of country perfumes. Instructors trained at the technical schools were sent to promising centres to give instruction in the working of hosiery machines; and the superintendent of one of the technical schools was deputed to inquire into the possibilities of developing the lamp trade. It is clear that the Industries Department of the provinces has developed rapidly of recent years, and the local government is much better prepared to further industrial progress. With the staff now at its disposal, sustained interest should take the place of the somewhat spasmodic efforts of the past.

A favourable opportunity has undoubtedly arisen for developing many of the industries, which must still be called minor industries, dealt with in the report. As to the best means of effecting this, opinions are likely to differ. It would appear from the *résumé* given of the views of those consulted that many, who might be in a position to influence public opinion, believed that nothing short of protection would be likely to benefit the nascent industries of the provinces. The arguments for and against this measure have been worn somewhat threadbare and need not be repeated. One point, however, history makes clear, namely, that protection will not necessarily turn a country to the path of industrialism, and, unless it has the effect of introducing keen internal competition, it is accompanied by serious disadvantages.

Something more than the introduction of import duties is required to convert an agricultural into an industrial community. A more practical controversy turns on the amount of direct assistance which can properly be given by Government to the development of the industries of the country. There is little doubt that the experiences of the past few months have accentuated the feeling that in the general interests of the country a larger measure of Government assistance should be given. Too great a dependence on other manufacturing countries for articles which have become practical necessities is not altogether a healthy state of things; and the cessation or diminution of supplies may result in a disorganisation of trade which may more than outweigh the advantages of buying in the cheapest market. England herself, the great protagonist of free trade, has been compelled in one well-known instance to recognise this. The official publication of imports from enemy countries and officially conducted inquiries as to the best means of capturing this trade have not unnaturally given rise to the question as to what assistance Government itself is prepared to give towards effecting this object. Government is being freely invited to declare its policy on the matter, and abundant suggestions are offered as to the form this should take, most of which do not err on the side of moderation. There is, however, one practical limitation to direct Government assistance. Once an industry has been started, a new enterprise can only under ordinary circumstances be aided to the prejudice of those already in existence. This limits Government's interference in a large measure to pioneering industries. Until what may be termed its experimental stage has passed—that is, until its fitness to its environment is proved—there can be little valid objection to such assistance on the grounds of interference with private enterprise or of affording artificial support. The fact that Government has to intervene at all is evidence of a lack of private enterprise in this particular branch. The charge of spoon-feeding can hardly apply to an industry on its trial. The writer of the report has considered it necessary to justify at some length a recommendation for a subvention from the local government to a glass factory, on the ground that the proprietor is spending money on training unskilled labour, which will probably be drawn on by other factories if this one proves a success, and that the said labour is wasting a good deal of valuable material. To gild the pill which may otherwise have an unsavoury look, it is suggested that the grant be made on the condition that the proprietor takes in a certain number of apprentices. But, as Government is coming forward to bear part of the expenses ordinarily borne by the pioneering capitalist, it is not very material which of those expenses is borne, or in what form the aid is given. The main point is whether the industry, if established, is likely to prove of public benefit: if this is the case, and private enterprise is unlikely, owing to initial risks or expenses involved, to establish it unaided, Government would appear justified in coming to its assistance.

An unfavourable comparison is not unfrequently drawn between the rate of progress made in India and in other countries, such as Japan, which started late on their industrial career. It is, however, frequently overlooked that India is a rich country agriculturally, and that indigenous business talent has continued to devote itself mainly to trading in agricultural produce. In inland provinces capital remains concentrated in the hands of the business and banking classes, who, as a body, have shown little tendency to invest it in industrial undertakings. Indian capital is in fact being very slowly diverted into industrial channels. The demand for more rapid progress in developing the industries of the country comes largely from the educated classes, who, apart from patriotic sentiment, are actuated by the very reasonable desire to enlarge the number of careers and professions open to them. To a certain extent the insistence on the necessity of

Government aid is attributable to this cause; for men who have gone through a modern education with a view to entering a profession have usually not the capital necessary for embarking on industrial ventures. But for more rapid progress it is necessary that the capitalist class should show greater readiness to leave the beaten track. Government can pioneer industries; but little purpose will be served unless capital is forthcoming to develop them. The United Provinces have rich agricultural resources. As is pointed out in the report, the production of oil-seeds of various kinds is on an enormous scale; but so far "oil-crushing plants operated by modern machinery can be counted on the fingers of one hand." The area under cane exceeds a million acres; but the provinces still import most of their sugar. In spite of the large area under cotton, most of even the cheap cotton goods come from outside. The utilisation of these resources affords ample opportunities to the capitalist. Lack of requisite training undoubtedly hampers members of the trading and banking classes in turning to industrial pursuits; they are for the most part ignorant of the working of modern machinery and of factory routine, and have little experience in the management of men. But such difficulties, as the Parsee community have shown elsewhere, are not insuperable. Probably in this, as in other matters, we have to look to the initiative of a few far-seeing individuals: in commerce success is apt to breed a number of competitors. For such men there is a wide field awaiting exploitation.—*The Pioneer Mail.*

AN ANCIENT TEUTON COLONY IN ITALY.

While Italy is fighting for the restoration of Italian-speaking tracts on the Trentino, it is curious to note that, on the south side of the frontier, there is a linguistic and ethnic anomaly of a reverse character—a Teuton-speaking colony concentrated on a plateau ensconced amid the Italian mountaineers north of Vicenza and Venice. This curious settlement, according to traditions which not so long ago lingered amongst them, consisted of the descendants of the ancient Cimbri, who were the earliest in the long line of Teutonic invaders of Rome. In 101 B.C. these northerners were broken up in battle by the great Caius Marius and dispersed along the border lands of northern Italy. The Cimbri colony is called I Sette Communi, a few miles from Bassano, a pretty town on that picturesque Alpine stream, the Brenta, which dashes down the rough declivities on its way to the Adriatic. Beyond Bassano lie two towns, Oliero and Valstagna, where the road becomes difficult for wheeled traffic, and mules have to be hired for the further mountain ascent. To an American traveller who explored these parts about half a century ago an Italian guide was here assigned, Count Giovanni Bonnato, who, in spite of his patrician origin (the name is the same as that of the historian of the Sette Communi), was not too proud to undertake the charge of the party, and whose friend, the owner of the mules, was a genuine Cimbrian with a broad sheepish face and a heavy awkward accent of Italian, marking his northern race. It was a lovely morning; the Alps rose crest on crest around, and ahead was the Cimbrian village of Fozza with a white chapel gleaming from the heart of a lofty grove. Under a spreading haw tree, halfway up the mountain, a rest was called for, and here the Count Giovanni and the Cimbrian foregathered. The latter's name in his own tongue was Bruck, which in compliment to his qualities of good-fellowship was converted by the American into Brick. His assurance was that the Capo-gente, or head of the clan at Fozza, could give all information about the Cimbri. From the information supplied to them the travellers essayed to compile a vocabulary of Cimbrian words with their English and German equivalents, and in spite of some very curious dissimilarities the general affinity to the Teutonic roots was very apparent. The village of Fozza boasts about thirty houses and is one of the smallest of the Sette Communi, while the capital, Asiago, contains some thousands of inhabitants and lies more to the west in the direction of Vicenza. The church at Fozza, like the other edifices, was built of stone; and the village at a little distance might look like broken crags of rocks, so well did it consort with the harsh, crude nature about it. Meagre meadow lands, pathetic with tufts of a certain pale blue tearful flower, stretched about the village and southward along the approach from the plains.

At the humble door of the Capo-gente the party entered his dwelling at his wife's invitation and seated themselves near the welcome kitchen fire, though the sunny Lombard plain below was purple with grapes and black with figs. There was a melancholy wail which the peasants iterated ever and anon—"Ah, my lords, is it not a miserable land here?"—and while some eggs and wine were being produced for refreshment the Capo-gente came in. He was a very well-mannered person, but had of course the bashfulness naturally resulting from a lonely life at that altitude where contact with the outside world is infrequent. His fellow-townsmen seemed to regard him with a kind of affectionate deference. He stood till invited to sit down, and presently consented to take some wine with the strangers.

A tradition existed among them, so he said, that their ancestors had fled to those Alps from the Roman general Marius, and had dwelt for a long time in the hollows and caves of the mountains, living and burying their dead in the same secluded places. At what time they had been converted to Christianity he could not tell: they had up to the beginning of the nineteenth century little or no intercourse with the Italians. Formerly they did not intermarry with that race, and it was seldom that any Cimbrian knew its language. But in later times intermarriage had become very frequent, and

Cimbrian was gradually falling into disuse. They still, however, had books of religious instruction in their ancient tongue, and until comparatively lately the services of their church were performed in Cimbrian.

Two of the books were brought forward for inspection, one a catechism for children entitled "Dar Kloane Catechism vor z' Boloseband vortraghet in z' gaprecht von siben Komünen in vier Halghe Gasang, 1842. Padova." The other, a more elaborate work, was called "Johann Andreas Schroeller's Cimbrisches Wörterbuch. Josef Bergman. Vienna. 1855." The author of this book had dwelt for a week in these parts, compiling a dictionary, a copy of which he had sent to the Capo. The total number of the Cimbri was, according to the general belief, nearly ten thousand.

Asiago is generally held to be the chief headquarters, and is now frequented more or less by visitors from Venice as a summer resort. At Oliero the count's services as guide were gratefully dispensed with and a small honorarium bestowed on him. It turned out he was a member of a fairly wealthy family of rank in Venice, and that while he served in the army he had received an allowance from his kinsmen, but that at other times he earned what he could as guide and cicerone to summer tourists and visitors.

More recently a visit was paid to the highland district of the Sette Communi, about twenty years ago, by an American traveller, Mr. W. D. McCrackan, who approached the tract from the west and succeeded in amassing some very interesting data in the course of a lengthened and careful investigation. He points out that visitors from the outside world have always been rare, in spite of the fact that the great route from Verona to Innsbrück over the Brenner runs close under the precipices to the west and east, the favourite road into the Dolomites from Bassano. The traveller remarks that in the land of the Sette Communi the eye roams for many miles east and west over a rolling highland, green and joyous as of the north, spanned by a southern sky. Here and there clusters of houses appear on smooth knolls of ground; men are seen mowing, and rows of women keep time with a rhythm of rakes; herds of cattle graze near and far, the whole forming an idyllic dairy district, surrounded by a woodman's paradise. The houses of the villages and hamlets in the Sette Communi are distinctly un-Italian in appearance. For the most part they are thatched or shingled and peak-roofed, in order to shed the snow in winter, betraying an almost Gothic tendency.

Mr. McCrackan estimated the total population as over 30,000, the greater number being engaged in cattle-breeding, cutting timber, charcoal-burning, and straw-platting. Many of the men go out into the world to peddle pictures of saints and religious books, leaving the women to do the field work.

Most of the documents relating to the period from the tenth to the fifteenth century were lost in a fire at Asiago, which is considered the chief of the villages. Since the fall of the Venetian Republic the remaining archives have for the most part been scattered to the winds, stolen, burned, or used as wrapping paper in meat or sausage shops.

Italian scholars of the seventeenth century, and even later, generally accepted the theory of a Cimbrian origin. An amusing story is told of Frederic IV., King of Denmark and Norway, who paid a visit to Asiago in 1709. It appears that while travelling incognito in Italy as Count of Oldenburg and accompanied by a suite of fifty-four courtiers, he made a stay of a week at Vicenza. On one occasion his courtiers, strolling about the town, were surprised to come upon some men speaking a German dialect. Upon inquiry, the peasants explained that they were from the Sette Communi and were speaking Cimbro. That evening, at dinner, the curious meeting was mentioned in conversation, and next day Frederic, as king of the land which was supposed to be the original seat of the Cimbri, decided to pay a visit to the interesting upland. His cavalcade of Danish and Italian noblemen were received with acclamation by the peasants of Asiago, cries of "Evviva il re dei Cimbri!" resounded on all sides, and local hospitality put its very best foot forward.

Until the seventeenth century the priesthood of the Sette Communi had been recruited almost exclusively from German-speaking native families. But from the moment that the Italian clergy displaced German priests Cimbro was to all intents and purposes superseded. A striking peculiarity of the dialect is the constant change of "v" sounds into "b," *i.e.*, "wir sind" becomes "bir sain." An old man said to Mr. McCrackan at Asiago, "Do you know what we call Verona here? We call it Bern." This recalled the fact that Theodoric the Great, because he sometimes resided at Verona, was known in the German hero romances as Dietrich von Bern. Also may be mentioned the fact that Bern, the capital of Switzerland, was founded by the Dukes of Zaeringen, who had once possessed the Margraviate of Verona, which would seem to indicate that they may have named their new city in memory of the old.

Underneath the big sundial on the wall of the great parish church at Asiago is a Cimbro inscription: "Ich Schbaige, Benne De Lichte Vehlmar, Un Selten Rede, Aber Bahr" ("I am silent when the light fails me, and seldom speak but true").

A proof of the surprising independence of the Sette Communi is afforded by their so-called Nunzi, officials maintained by them in the principal cities of the Venetian Republic to watch over their interests, after the manner of modern consuls. They elected their own judges, and their only obligation was to defend their mountain passes against the foreign foes of Venice. One relic of strong Teutonic influence lies in the common ownership of field and forest. It is administered by the Spettabile Consorzio dei Sette Communi, a body which is the lineal descendant of the Reggenza of Venetian days.

SUGAR INDUSTRY IN THE PHILIPPINES.

The *London and China Telegraph* mentions that, according to a report by Mr. J. F. Boomer, U.S. correspondent at Manila, the first application for Government funds under the provisions of the Sugar Central Act has been received by the Sugar Central Board for the establishment of a "central" at Lagonoy, Ambos Camarines. The request is for $750,000. By the terms of the Act, the applicant must invest an amount equal to that asked from the Government. The Board will visit the section in which it is proposed to establish the central to investigate the conditions.

The farmers of Batangas Province are preparing for an unusually large planting of sugar for the coming year. This increased planting is inspired somewhat by the rising price of sugar and more, perhaps, by the efforts of the representatives of the new large sugar central at Calamba, which is prepared to transport the cane of the farmers from the fields, in Batanga, along the railroad to the central, manufacture it into sugar, and give the farmers as high as 30 per cent. more sugar per ton of cane than they have ever been able to get before. The central company is prepared to lay spurs of track from the railroad to the fields to transport the cane. It is impossible at present to estimate with any degree of certainty the increase in planting that the year will show in the province, but the indications are that it will be very great.

The Bureau of Agriculture is endeavouring to introduce a Hawaiian variety of sugar-cane in the Philippines. Already it has been planted to a considerable extent in Negros. Nurseries for propagating this cane have been started in several parts of the islands, and the planters are taking to it readily. In March, 1914, a quantity of points of the Hawaiian cane from the Government's experiment station at La Carlota, Negros, were taken to Vigan, and set out in ordinary rice land at Bantay, Ilocos Sur. These points were planted on the land of a co-operator of the Bureau of Agriculture, and the cane produced from them was so much superior to the cane theretofore grown in the vicinity that the planters eagerly sought for points for planting on their lands. All the product of the original planting was distributed in the community for seed. It is expected that the Hawaiian variety will soon replace the locally-grown canes in large and important areas of the islands.

NOTES ON BOOKS.

Discoveries and Inventions of the Twentieth Century. By Edward Cressy. London: George Routledge & Sons. 1914.

Though the twentieth century is not yet very old it is responsible for a good many inventions. Last year, in spite of the war, there were 24,820 applications for grants of letters-patent, and the average number of such applications may be taken now as 30,000 per annum. Allow that nine-tenths of these are old, worthless, or trivial, and we still have 3,000 a year, or, say, 40,000 since the century began. An account of all these would fill a big book, and it would take a clever author to compile it. Needless to say, Mr. Cressy has not undertaken such a hopeless task, nor has he attempted the quite practicable, if rather difficult, work of giving us any account of the different directions towards which invention has trended during the last fourteen years, if that particular period was thought convenient, which it certainly would not be.

As a matter of fact, a more accurate title for the book would be, "Some inventions of (shall we say) the end of the nineteenth and the beginning of the twentieth century," though it may be admitted that such a title might fail to attract many readers. As a matter of fact, "it was decided to deal with the characteristic features of development in certain selected fields of enterprise during the last twenty-five years." This has been done satisfactorily enough. The selection has been made with sufficient judgment, and the descriptions written with sufficient accuracy. The subjects include water-power, fuel, steam and other prime movers, generation and use of electricity, steel, workshop appliances, cold storage, liquefaction of gases. agriculture, railways, motor-cars, naval construction, aeroplanes, wireless telegraphy, recent development of photography, with, as a final chapter, "Radium, Electricity, and Matter." This is a diversified, not to say, heterogeneous collection: but those who seek information on the various subjects included will find it; and so far as the limited faculties of the critic qualify him to judge, the information seems correct and to be provided in an intelligible form. The book is very fully illustrated with pictures supplied, for the most part, by owners of the works or makers of the machines or appliances described.

GENERAL NOTES.

German Food Frauds in War.—The *Lancet* draws attention to some novelties in fraudulent foods which are being made in Germany in considerable quantities by manufacturers bent on taking advantage of the desire of relatives at home to send food and delicacies to their friends at the front. One of these is "solid alcohol," advertised as a substitute for alcoholic drinks. The specimens consist of cubes of gelatin, to which brandy and sugar have been added before the mixture has been solidified. The directions are to pour water on these cubes, whereupon one obtains (according to the *Lancet*) "a sweetish fluid, weak in alcohol, and possessing a rather disagreeable flavour of glue." Obviously, with the tendency of alcohol to evaporate swiftly, the longer these cubes are

kept the less is their alcoholic strength. One firm has gone so far as to introduce brandy substitutes and substances of a "peppery" nature to simulate the warmth of a dose of brandy, with the result that complaints have been received from soldiers of painful irritation in the mouth. Coffee and cocoa have also been sold in tablet form at most exorbitant prices, one brand in particular being sold at the rate of 12 marks per pound.

RUBBER PAVING.—Under the sanction of the City authorities, the pavement in front of the offices of the Malay States Information Agency at 88, Cannon Street, has been relaid with rubber tiles, the work being carried out to the order of the Agency by the Leyland and Birmingham Rubber Company, Ltd. These tiles are 12 in. square and half an inch thick, laid on a cement concrete bed, and when walked over give none of the jarring effect experienced from stone pavement. These tiles are manufactured from plantation rubber, and it is hoped one result of the experiment will be to popularise this form of paving, if not for the roadway at least for the foot pavements of our cities.

THE FORESTS OF SIBERIA.—Russia, according to the *Paper-Maker*, will be the world's timber-yard of the future, for no less than two-fifths of the empire is forest land. In European Russia the forests extend over an area of about 345,000,000 acres, of which 214,000,000 acres belong to the State, 88,000,000 acres to individuals, 26,000,000 acres to peasants, and 11,000,000 acres to the Crown, leaving 6,000,000 acres under diverse ownerships. In Asiatic Russia most of the forest land belongs to the State. A conservative estimate puts it at 636,000,000 acres, a low figure when it is remembered that much of the land is as yet unexplored. Thus vast reaches of the timber belt in the Yakutsk Province, bordering on the Arctic, which have never known the foot of civilised man, are roughly reckoned at 90,000,000 acres. The same is true of the vast forest areas in Eastern Siberia. It is safe to say that two-thirds of the timber land in the Russian Empire lies between the Urals and the Pacific. Of the total 636,000,000 acres owned by the State, 239,500,000 acres are being worked directly by the Government, with a yield of about 300,000,000 cubic feet of timber, producing gross receipts of $2,100,000.

THE SOUSLIK OR PRAIRIE MARMOT.—Attention is drawn by a writer in the *Times* Russian Supplement to the damage caused by the *souslik* or prairie marmot, which has long been a scourge to agriculture in the steppe regions of South Russia, especially on the Don, where it annually destroys as much as a quarter of the wheat crop. In 1913 special measures for dealing with the pest were devised at a conference convened by the Cossack Hetman, and all able-bodied members of the population of the province were required to participate under competent direction in the work of extermination. Some idea of the gravity of the danger may be obtained from the fact that in 1914 no fewer than 7,301,982 *sousliks* were destroyed throughout the province by water and upwards of 30 million burrows treated with sulphuretted hydrogen. Since the commencement of the war the majority of the able-bodied men in the province have been called to the colours, but the provincial commission sees no reason why women and children should not be enlisted in this work. It has, therefore, resolved to request the district commissions to compel the local population to deliver at stated periods a fixed number of *sousliks* in proportion to the extent of their holdings, and to recommend the use of sulphuretted hydrogen.

PALM-KERNEL CAKE AND MEAL.—Palm-kernel cake is a very popular cattle food in Germany, Holland, Denmark, and Scandinavia; but it is comparatively unknown in Great Britain. At a time when all foodstuffs are at a premium, it is desirable that British farmers should put aside their traditional conservatism and experiment in new directions. According to the Bulletin of the Imperial Institute, 1,600 tons of palm kernels, as well as 3,000 barrels of palm oil, were recently landed at Hull—the first consignment shipped thither from West Africa. Two products are obtained in crushing palm kernels, oil and cake. The value of the cake as a cattle food is very high, and analyses which have been made show that the cake manufactured in Britain is distinctly superior (owing, probably, to improved methods of crushing) to that made in Germany. Samples of British cake and meal may be seen at the Imperial Institute.

JAPANESE RAILWAY DEVELOPMENT.—H.M. Commercial Attaché at Yokohama reports that of the Imperial Government railways about 175 miles of new sections and about 150 miles of light railways were open to traffic during 1914. The most important sections were 25 miles on the Tokushima line, 23 miles on the Sakata line, and 20 miles each on the Murakami and Gwanyetsu lines. Two of the most interesting events of the year were the completion of the splendid new central station in Tokyo, and the opening of the new Government electric railway between Tokyo and Yokohama. This railway, which runs side by side with the existing steam track, is 19 miles long, and connects the two above-mentioned towns. Between the two termini there are 14 intermediate stations. Unfortunately the railway had only been in operation for a few days at the end of the year when it became necessary for the authorities to discontinue the service. As far as it is possible to ascertain, the whole of the trouble lay with the overhead equipment, which at the time of opening to public service was in an unfinished state, so much so that trial running of the trains was only carried out for about two days.

Journal of the Royal Society of Arts.

No. 3,273. VOL. LXIII.

FRIDAY, AUGUST 13, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

FOTHERGILL LECTURES ON "MOTOR FUELS."

The Fothergill Lectures on "Motor Fuels," by Professor VIVIAN B. LEWES, F.I.C., F.C.S., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor, Howard, and Fothergill Lectures, which have been published separately, and are still on sale, can also be obtained on application.

PETER LE NEVE FOSTER PRIZE.

Mr. Reginald Le Neve Foster has presented the Society with a donation of £140 for the purpose of founding a prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879.

The Council have determined to offer the prize for a paper on "Zinc, its Production and Industrial Applications."

The prize will consist of a sum of £10 and the Society's Silver Medal.

The paper for which the prize is awarded will be read at one of the Ordinary Meetings of the Society.

It is expected that some account will be given of the history of the metal, the sources of its supply, its metallurgy, and the various uses to which it has been, or may be, applied.

Intending competitors should send in their papers not later than December 31st, 1915, to the Secretary of the Royal Society of Arts, Adelphi, London, W.C.

The paper must be type-written. It may be sent in under the author's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges nothing deserving the full award is sent in.

HENRY TRUEMAN WOOD, *Secretary.*

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

OILS, THEIR PRODUCTION AND MANUFACTURE.

By F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.T.

Lecture I.—Delivered January 18th, 1915.

The word "oil" embraces a large number of compounds of widely differing characteristics. They all contain the elements carbon and hydrogen, or carbon, hydrogen and oxygen. Thus mineral oils, so called from the fact that they are chiefly obtained by drilling into the ground, consist of carbon and hydrogen, although they may contain impurities such as sulphur and nitrogen compounds, which it is the endeavour of the refiner to remove because they cause the oils to have an unpleasant smell and to become coloured on keeping. The presence of sulphur is particularly objectionable in oils employed for illuminating purposes, because when they are burnt sulphur-dioxide is produced and this becomes oxidised to sulphuric acid, which naturally is very harmful to the decorations in the room in which the oil is burnt.

Most mineral oils are found at great depths below the earth's surface, and are generally under very considerable gas pressure, so that when the drill strikes into the oil reservoir the oil is forced up through the drill-holes and forms spouts or gushers which at times rise to very considerable heights, and often before the drill-hole can be capped lead to very serious losses of oil.

The oil is found in a dip or trough known as a "syncline," which is arched over by a more or less impervious roofing called the "anticline." Owing to volcanic action during the formation or settling of the earth, contractions due to the cooling of the earth's crust occurred. These movements caused flutings in the horizontal strata which frequently produced curved formations. Where the stratum consisted of sand or limestone, impenetrable reservoirs were formed which were arched over by the anticline, and into these reservoirs under certain conditions oil found its way—probably, in fact, was produced *in situ*. The question will naturally be asked, From whence did the oil come? This brings us on to very controversial ground, since there are many theories as to the formation of mineral oil. Most authorities consider that the oil has been produced in the course of ages from organic matter, both animal and vegetable. There are others, however, who attribute its formation to the decomposition of carbides.

Probably at the commencement of the world's history vegetation and also animal life—naturally of a low order—flourished with a rapidity and superabundance which we at present cannot conceive. Vegetation, both land and marine, underwent the annual changes such as we know at present of death and decay, and animals, fish and insects lived and died. These organic materials slowly rotted and became covered up with the calcareous homes of marine organisms and with sand. Pressure thus became gradually exercised, and the internal heat of the earth acting at the same time caused rapid decomposition or distillation under pressure, and under these conditions natural gas and petroleum were formed. The gas and oils gradually collected in the syncline reservoirs, and were retained by the impervious structure of the anticline. The fact of the presence of nitrogenous and sulphur compounds accompanying the crude oil seems to point to a vegetable and animal origin for mineral oils. When we refer to animal life we do not necessarily refer only to low forms such as minute marine organisms, but to all forms of animal life, particularly to whales and other inhabitants of the sea, which are known to contain large quantities of oil. Whale oil, indeed, has a quite different character from mineral oils, but under the joint action of heat, pressure and moisture would probably be split up into hydrocarbons of similar character to mineral oils. Then, again, the decay of the enormous quantities of seaweed was probably a great source. In the warm seas it must have flourished in superabundant luxuriance. Even to-day in our cooler seas the growth is immense. In the Red Sea, for instance, steamers often pass through miles and miles of floating seaweed, which is of such depth and so closely packed as often seriously to decrease their speed. It is reported that in 1890 a steamer took fifty-seven hours to pass through a mass of seaweed in the Red Sea. Rather more than 100 years ago the bulk of the potash salts and of iodine and bromine was manufactured from the derelict seaweed thrown up on the shores. This gift of the ocean is now only used to a small extent, and is allowed to become the sport of the waves. Then, as to terrestrial vegetation—when peat and lignite are distilled, gases, oils and solid paraffin are obtained, and these oils are contaminated to a greater or less extent with impurities similar to those found in mineral oils.

Another theory of oil formation is that metallic carbides account for the formation of hydrocarbon gases and mineral oil, it being suggested that various carbides were produced by the interaction of carbon and metallic oxides under the very high temperature then prevailing. These then came in contact with water or with superheated steam under pressure, and hydrocarbon gases and oils were produced. Under the conditions of high temperature and pressure these gases might become polymerised to form higher hydrocarbons, or there might be a catalytic action between hydrogen and acetylene and other unsaturated hydrocarbons by coming into intimate contact with the presence of nickel, iron or cobalt. Sabatier, indeed, has shown that in the presence of certain metals acetylene and hydrogen can be converted into hydrocarbon oils similar to those obtained from the earth. Thus, for example, by heating acetylene for twenty-eight hours in contact with finely divided nickel, Sabatier obtained 20 cubic centimetres of a liquid oil having the smell of petrol. It should be pointed out, however, that the nickel has to be in a specially active state—a condition which would hardly be found in the nickel as it occurs naturally.

It has been shown by Engler and others that most mineral oils are optically active, and on fractional distillation it is found that, generally speaking, the portions which distil below 200° C. are inactive, but that those between 250° and 300° C. are active, and turn the ray of polarised

light to the right. Thus a Baku oil gave a dextro-rotation of 16°, a Galician 25°. The optical activity of Russian, Galician and German oils is greater than that of those from the United States. I draw attention to the optical activity of mineral oils because it proves that such oils must have a vegetable or animal origin. Oils obtained from carbides or by catalytic action of metals on acetylene, ethylene, etc., would not be optically active.

It is not my intention to go further into the possible derivation of mineral oils, as this was treated in so thorough and masterly a way by Professor Vivian Lewes in his paper on Liquid Fuels, read before the Society this time last year.

Although it is only during the last fifty or sixty years that the production and refining of mineral oils has been a great industry, oil obtained from shallow wells or from exudations on the surface of the earth has been known practically ever since the earth was inhabited. In Genesis it is stated that Noah was commanded to pitch the ark within and without with pitch (Gen. vi. 14). Natural pitch has been produced by the evaporation of the lighter products of petroleum, and by the oxidation and polymerisation of the heavier portions. The slime which the builders of the Tower of Babel (Gen. xi. 3) had for mortar is supposed to have been asphalt or bitumen brought down by a tributary of the Euphrates. Again (Gen. xiv. 10), "The Vale of Siddim was full of slime pits," into which the Kings of Sodom and Gomorrah fell when they fled after being defeated in battle. They apparently did not get out again, because "they that remained fled into the mountain." The word "slime" here mentioned appears in the Vulgate as bitumen. In various other places in the Bible, both in the Old and New Testaments, reference is made to oil or bitumen. Pliny and other writers of his time mention the use of Sicilian oil for illuminating and medicinal purposes. The asphalt or bitumen in the neighbourhood of the Dead Sea was collected and sold into Egypt in the time of Julius Cæsar for embalming bodies. According to ancient records of Japan and China, natural gas and petroleum were employed for illuminating purposes hundreds of years before the Christian Era.

The oil of Baku had apparently been known from the earliest times, and Marco Polo, writing towards the end of the thirteenth century, refers to "a fountain from which oil springs in great abundance." He also mentions that the oil is not good to use with food, but is good to burn, and is used to anoint camels that have the mange. . . . In the olden days, before petroleum was obtained in large quantities, it was frequently used in surgery and medicine and was highly prized. This is a particularly interesting fact, because vaseline and specially prepared petroleum are to-day used as an ointment and for internal purposes in very large quantities. In England inflammable gas was mentioned in 1667. In 1739 Dr. Clayton refers to a pitch which burnt like brandy, and by the flame of which eggs could be boiled. A petroleum from Pitchford was used for burns, rheumatism, etc., under the name of "Bettons oil."

The historical aspect and the gradual building up of a huge industry from small beginnings is always a most interesting and fascinating subject, but it is not possible for me with the time at my disposal and the vast subject to be dealt with to go into minute detail. Suffice it to say, that until about the middle of the last century the mineral-oil industry was of very small dimensions. Then in America, when boring for salt water to be used for the manufacture of salt, source after source of natural gas and petroleum was struck. At first this was a cause of annoyance, and the problem was how to get rid of the oil and obtain the pure salt water. In fact, salt wells were often abandoned because of the infiltration of oil.

Long before the production of petroleum became an American industry it was known to the Indians who dwelt there. Ancient oil wells, sometimes centuries old, have been found in the neighbourhood of Oil Creek in Pennsylvania. Before it was employed as an illuminant, petroleum was used in America as a cure for rheumatism, burns, sprains, etc., and was called "Seneca oil," as it was obtained from the vicinity of Lake Seneca.

Although it was known that oil existed under large areas of land in America, it was not first produced from this source, but from the destructive distillation of shale and coal by Young's process for some considerable time before the natural product, which was afterwards obtained in such prolific quantities, was worked. Indeed, shortly before the development of the mineral-oil industry from fifty to sixty shale refineries were in operation in America. Young's process being a British invention, we may claim that the oil industry originated in Great Britain. It was about 1858 that artesian wells were first drilled with the object of obtaining oil. Shortly

afterwards remarkable results were obtained, and the "oil fever" took possession of the American continent. Huge profits were made and great fortunes lost before the industry settled down to steady production. At first, owing to very crude methods of refining, there was little sale for the oil, and consequently the market was glutted, and enormous quantities of oil were allowed to run waste simply because it did not pay to collect and store it. The following quotation from Sir Boverton Redwood's work on Petroleum and its Products places the early position of the petroleum industry in a nutshell: "In 1859 the total produce, which was wholly obtained from Oil Creek, was 2,000 barrels. In June, 1860, the wells along Oil Creek yielded about 200 barrels daily, and in September about 700. The yield then rapidly increased owing to the discovery of flowing wells, until during the winter and spring of 1861 to 1862 it amounted to about 15,000 barrels daily. The price obtained for the crude oil then fell so low that production was largely arrested, until the production of 1863 was scarcely half that of the beginning of 1862, and that of 1864 still less. In May, 1865, the production had declined to less than 4,000 barrels a day, the Valley of Oil Creek being the only producing locality at the time. It is estimated that some ten million barrels ran to waste in Pennsylvania prior to 1862 owing to the absence of a market."

In the younger days of the industry the problem—always difficult—of capping a powerful gusher was much more formidable than it is now, because as the industry has progressed so the skill and resource of the engineers have also advanced. Even to-day, however, very large quantities of oil frequently run to waste, owing to the difficulty of capping and arresting the flow after oil has been struck.

An oil-field having been discovered, either accidentally or from geological surveys, the geologist prospects and chooses the most favourable position for the engineer to put down a test bore-hole. When an anticlinal structure is located on the surface the choice of position is fairly obvious; but in many cases the position can only be inferred from the examination of a number of data, and the choice becomes a matter of difficulty. The facts that there are external indications of petroleum, such as oil scums, on the surface of water pools, or that bitumen is found in the neighbourhood, or that natural gas escapes, do not necessarily point to supplies of petroleum existing under the earth. Bituminous or asphaltic deposits point to the fact that at one time petroleum existed in the district, because they are produced by the oxidation and polymerisation of the heavier portions of the oil after the lower fractions have evaporated off. They may, however, have been produced by the fracture of an anticline, and all the light oil originally present may have evaporated off, and the remaining heavier portions have been converted into pitch. On the other hand, only a portion of the oil may have thus been lost, and bores may show the presence of hidden reservoirs below. Having located a likely spot for drilling, a shaft 8 to 10 ft. square is sunk through the surface soil. When the bed-rock is reached drilling is commenced. As the drill cuts down the bore-hole is cased by means of a steel tube which is tapered down as the drill reaches deeper and deeper depths. When oil is struck the flow may be gradual and may require pumping, or there may be a gush of gas, sand and oil which will produce a geyser-like fountain, and sometimes drives out the drilling tools before its impetuous flow.

The quality of the oil varies very much: it may be a thick viscid liquid or a more or less limpid fluid. It must not be supposed that a golden yellow or colourless liquid is spouted out. This is very rarely the case. The natural oil is generally dark brown and thick, or may be black in colour, and it is only after refining that burning, lubricating and the various qualities of oil which are found on the market are obtained. A very remarkable oil which is almost colourless has been found at Dingham Well in Canada, but it is obtained only in small quantities. This oil is a thin, limpid, light yellow liquid, and contains a large quantity of oil suitable for light motor-engines. Indeed, it has been used on motor-cars directly as obtained from the well and without previous refining. A sample which I received gave the following fractions at distillation. The specific gravity of original oil was 0·7508 and the initial boiling-point 52° C.

I. Distilled up to 150° C. . 72·8 per cent.
Specific gravity, 0·7300.

II. 150° to 270° C. . . . 24·8 per cent.
Speci c gravity, 0·7985.

Above 270° C. a semi-solid residue of 2·7 per cent.

It is possible that on drilling deeper a heavier oil will be obtained from which this oil has been distilled by internal heat. One may suppose that the lighter fractions of a heavier oil have been distilled off, and have condensed and

collected into a pocket, which is the well at present struck.

In some districts oil is found comparatively near the surface. In others, bore-holes of great depths have to be sunk before oil is reached. Thus in Baku, where wells were first sunk, oil was encountered in some parts at a depth of about 150 ft. Now that the fields have become more or less exhausted, much deeper drilling is necessary. In Galicia oil is not generally tapped until a depth of 3,000 to 4,000 ft. is attained. The greater the depth, naturally the greater the initial expense incurred before the wells are producing. The original Burma wells which were dug by the natives were also comparatively shallow. In some districts oil can be ladled out of quite shallow holes. The object of casing the drill-hole is to prevent the wall of the hole from caving in and to keep out the water. If a well is about 2,000 ft. deep, the diameter of the casing at the top is usually at least three times the diameter of the casing at the bottom. The oil having been struck is led by means of pipes into reservoirs, which are often in the first place formed in natural hollows by damming. Here the oil separates from sand and water and becomes in a condition to be taken to the refinery.

The crude oil consists of a mixture of a large number of hydrocarbons. The proportions of heavy and light oils vary very much and are dependent upon the source of the petroleum. The lighter hydrocarbons have a lower boiling-point and a lower specific gravity than the heavier; therefore they can be more or less readily separated by means of fractional distillation. As, however, the boiling-points of the various compounds lie very close together, the pure individual hydrocarbon is never obtained commercially. By very careful and laborious fractionisation in the laboratory a large number of pure hydrocarbons have as a matter of fact been isolated, but there would be no object or advantage in doing this commercially.

The different classes of hydrocarbons met with may be briefly described under three heads: Methane, or paraffin hydrocarbons, which are the most stable of all, and the most difficult to oxidise or to act on chemically; the Ethylene, or olefiant hydrocarbons, which are more readily acted upon by chemical agencies and more readily oxidised; and the Naphthenes, which may be looked upon as hydrogenated benzenes, and are also very stable and difficult to oxidise or to decompose. Thus the methane and naphthene hydrocarbons are hardly attacked by strong sulphuric acid, but the ethylene hydrocarbons dissolve in the concentrated acid. The lower members of the methane and ethylene series are gases, and particularly gases of the methane series are contained in the gases which accompany most naturally occurring oil. In the following tables the boiling-point and specific gravity of a few members of the methane and ethylene groups are given:—

METHANE SERIES.

	Formula.	Specific Gravity.	Boiling-point.	Melting-point.
Methane	CH_4	0·415	−164° C.	..
Butane	C_4H_{10}	0·600	+ 1° C.	..
Hexane	C_6H_{14}	0·6603	+ 69° C.	.
Heptane	C_7H_{16}	0·683	+ 98·3° C.	..
Tetradecane	$C_{14}H_{30}$	0·775	+252° C.	+4° C.
Octadecane	$C_{18}H_{38}$	0·777	+317° C.	+28° C.

ETHYLENE SERIES.

	Formula.	Specific Gravity.	Boiling-point.	Melting-point.
Ethylene	C_2H_4	0·6095	−102° C.	..
Butylene	C_4H_8	666	− 5° C.	..
Hexylene	C_6H_{12}	0·683	69° C.	..
Heptylene	C_7H_{14}	0·703	123° C.	.
Decylene	$C_{10}H_{20}$	0·7512	172° C.	..
Octadecylene	$C_{18}H_{36}$	0·791	*179° C.	+18° C.

* Boiling-point at a pressure of 15 mm.

The difference between the methane series and the ethylene series is that corresponding members of the latter series contain two hydrogen atoms less than the members of the methane series, and are, therefore, said to be unsaturated. In the methane series all the affinities of the carbon atom are satisfied by

hydrogen. It is, therefore, only possible to act upon it chemically by replacing one or more of the hydrogen atoms by some other substance. It is, however, very difficult to turn out the atoms of hydrogen and substitute some other element. Therefore hydrocarbons of the methane series are extremely stable. On the other hand, owing to the hydrocarbons of the ethylene series being unsaturated, they are much more readily attacked by chemical agents, and are, therefore, more readily oxidised Take, for example, the hydrocarbons butane C_4H_{10} and butylene C_4H_8, which may be written more fully $CH_3.CH_2.CH_2.CH_3$ and $CH_3.CH_2.CH=CH_2$. We notice that butylene, which belongs to the ethylene series, contains two hydrogen atoms less than butane, and that there it has a double union or bond. It is at this point that butylene is most readily attacked, and it is the presence of this double union which makes it more readily oxidised and chemically active than butane. Thus on fractionisation the methane or paraffin hydrocarbons can be distilled without decomposition, but with the ethylenes decomposition and splitting commence with the hydrocarbons above $C_{12}H_{24}$. To prevent this they are often distilled in a vacuum.

The naphthenes belong to another series of hydrocarbons, in which, instead of the carbon atoms being joined together in the form of a chain, they are connected in a ring formation, thus:—

Naphthene Series.	*Methane Series.*
$\begin{array}{l} CH_2 \diagdown \\ \vert \quad\quad > CH_2 \\ CH_2 \diagup \end{array}$	$CH_3.CH_2.CH_3$
Cyclopropane. (C_3H_6)	*Propane.* C_3H_8
$\begin{array}{l} CH_2.CH_2 \diagdown \\ \vert \quad\quad\quad\quad > CH_2 \\ CH_2.CH_2 \diagup \end{array}$	$CH_3.CH_2.CH_2.CH_2.CH_3$
Cyclopentane. (C_5H_{10})	*Pentane.* (C_5H_{12})
$\begin{array}{l} CH_2.CH_2.CH_2 \\ \vert \quad\quad\quad\quad\quad \vert \\ CH_2.CH_2.CH_2 \end{array}$	$CH_3.CH_2.CH_2.CH_2.CH_2.CH_3$
Cyclohexane. (C_6H_{12})	*Hexane.* (C_6H_{14})

The following are the boiling-points and specific gravities of a few of the naphthenes:—

Substance.	Boiling-point.	Specific Gravity.
Cyclopentane C_5H_{10}	51° C.	0·7506
Cyclohexane C_6H_{12}	81° C.	0·7788
Cycloheptane C_7H_{14}	117·5° C.	0·8253
Nononaphthene C_9H_{18}	136° C.	0·7808

The naphthenes are much more stable than the ethylenes—in fact, almost as stable as the methanes. We generally use the terms paraffins, olefines, and naphthenes for these three classes of compounds. The proportion of these different series of hydrocarbons in the oils depends upon the locality from which the oils are obtained.

Besides the hydrocarbons mentioned, there are sometimes also small quantities of aromatic hydrocarbons, such as benzol and its homologues, and traces of terpene-like bodies. There are also present oxygenated bodies or phenols and nitrogen compounds, the latter having generally a very unpleasant odour. These bodies are removed in the process of refining. Sulphur bodies are usually present, and are frequently very objectionable; but, unfortunately, they are difficult to eliminate, and, if present in large quantities, add to the expense of refining.

Galician and Caucasian petroleum contains large quantities of naphthenes, whereas American oil consists largely of paraffins. Shale oil, on the other hand, and oils obtained by low temperature carbonisation of coals, peat, etc., contain a large quantity of olefiant oils.

It will be noticed that the specific gravities of the hydrocarbons of the ethylene and naphthene series are considerably higher than those of the methane series. This is due to the fact that the hydrocarbons, which are richer in carbon and contain less hydrogen, always have a higher specific gravity. On the other hand, the melting-points of the saturated hydrocarbons are higher than those of the unsaturated series, as, for example, octadecane melting-point, 28° C., and octadecylene melting-point, 18° C.

Refining the Crude Oil.

As already mentioned, most natural oils require to be refined before they can be used in commerce. The first process of refining is one of distillation. The oils are run into large cast-iron stills which are first gently and then strongly heated. At low temperatures low boiling oils of low specific gravity and flash-point distil over, and as the temperature is increased intermediate oils and, finally, lubricating oils and paraffin wax are obtained.

The fractions may be roughly divided into—

1. Petrol.
2. Solvent oils.
3. Illuminating oils for lamps.
4. Solar oils or gas oils.
5. Lubricating oils.
6. Paraffin wax (generally in the first place mixed with lubricating oil).

In the retort asphalt remains, or, if the distillation is pressed further, coke or retort carbon (which, as it contains very little ash, is valuable for the manufacture of electric-light carbons and electrodes).

As all natural oil contains certain quantities of water emulsified with it, great care has to be taken at the commencement of the distillation to prevent frothing, which would cause the oil to foam over into the condensers. At the beginning of the distillation a mixture of light oil and water passes into the receiver, and until the water has all been driven off the temperature of the oil in the retort will not rise much above 100° C.

The distillation is usually conducted in two stages, the first consisting in the removal of the more volatile fractions, and the second distillation, generally conducted in separate retorts, to produce lubricating oils and paraffin. In Russia a continuous process of distillation is largely practised, the crude oil being supplied to the still as rapidly as the oil is distilled off. The original American stills were completely bricked in; but after it was found that larger yields of light fractions could be obtained by allowing the condensed oil to drop back into the hot oil in the still, the tops have been left uncovered. This allows a portion of the oil to condense on the dome of the still and to drop back; it is thus "cracked" into lighter fractions. Cracking and cracking processes will be referred to later. As a matter of fact, whether or not it is advisable to crack an oil depends upon the class of oil which is most required by the market. If, as was the case before incandescent gas and electric light came into such general use, oil for illuminating purposes was required, then cracking produced a much higher proportion of this product. Kerosene was then the most valuable product. To-day it is not so. Motor spirit, fuel oil and lubricating oils are the most sought after products. At one time petrol had hardly any market value; it had to be eliminated from the kerosene, and we were constantly reminded that this was not efficiently done by the cry of the "deadly low flash." The producers naturally preferred to leave it in because the bulk of kerosene was increased and they got rid of a spirit which otherwise was a drug on the market. The chief use in those days of the very low boiling fractions was for so-called dry-cleaning purposes and as solvents, for which objects the demand was naturally limited.

It is difficult to give exact figures of the fractions, as they vary with the class of oil dealt with. Motor spirit is usually the fraction up to 150° C., but it is sometimes carried up to 160° C. Kerosene generally distils between 150° C. and 240° C.; Fuel oil from 170° to 300°; but if there be much paraffin wax present it may not be possible to take it to so high a temperature. Lubricating oils generally require to be distilled in a vacuum to prevent cracking.

After distillation the several fractions are treated with sulphuric acid and caustic soda to remove the impurities, and sometimes they are subsequently redistilled. When a large quantity of phenolic bodies is present, the first treatment is with caustic soda to remove them. The oil is then washed with water, about ½ per cent. of strong sulphuric acid is added, and the oil and acid thoroughly agitated. The mixture is then allowed to settle, when the acid falls to the bottom and can be run off. A second portion of acid is then added, the proportion depending upon the quality of the oil which is being refined. The first portion of acid acts chiefly as a dehydrating agent, so that when the second portion is added the oil is dry and the acid is not diluted. With the heavier oils of high boiling-point the agitation and mixing of the acid and oil are done by means of compressed air. With light oils such as petrol this would cause loss of some of the lower fractions; therefore the mixture is agitated mechanically or washed by a gravitation method.

There is always some danger of the emulsifying of the oils with the alkali and water washings, particularly when dealing with heavy lubricating oils. Consequently, great care has to be exercised in conducting the agitation. Generally separation takes place better if the oil is kept warm, which may be done either by means of steam coils placed within the agitator or by having the agitator jacketed. As soon as the bulk of the water has separated it is run off, and the oil is transported to shallow jacketed pans, where it is heated to the boiling-point of water until the frothing ceases, indicating that the water has all been driven off.

In order to get over the emulsifying difficulty and to have a continuous process, agitation is sometimes dispensed with. The oil is caused to flow through successive vessels which contain respectively sulphuric acid, soda lye, and water, and finally through a mixture of sawdust and salt in order to dry it. This process is used for treating the lighter fractions. Closed iron vessels are employed which are half filled with the reagent, and arranged in steps so that the

spirit will pass through by gravity. The spirit placed at a higher level is run by means of a perforated tube to the bottom of the first vessel, which contains sulphuric acid, as do the two succeeding vessels. The spirit, being much lighter than the acid, passes through it and rises to the top. It is then run through the succeeding vessels of acid, lye, and water, and finally through the filter. The methods of refining vary to a certain extent according to what products are chiefly required. Thus, when illuminating oils such as kerosene, having a specific gravity of 0·800 to 0·810, were fetching good prices, the American process was to endeavour to obtain as high a yield as possible of this fraction. As already pointed out, when a heavy oil is distilled more or less decomposition, technically called cracking, takes place, and oils of lower gravity and boiling-point are obtained. This fact was accidentally discovered in America in 1861. The man in charge

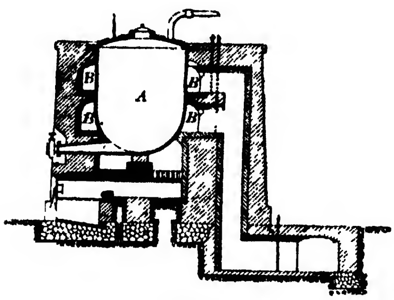

FIG. 1.

of a still had occasion to leave, but expected to return within an hour. He was detained, however, and did not return for some hours. Before leaving he had made up a good fire under the still; the oil, which was distilling over when the man left, had a gravity of 0·809—that is, was an ordinary kerosene oil. On returning about four hours later he noticed that a thinner oil was distilling with a gravity of 0·786. This, of course, was difficult to understand, as it was against preconceived ideas and practice. The manager of the works was called, and by this time a still thinner oil was distilling, having a gravity of 0·769. On consideration, and then by experiment, the manager found that the oil had been condensing on the top of the retort and falling back into the hot oil in the still. This caused a breaking down of the molecules and lighter oils were obtained. At this time illuminating oils were the most valuable products obtained from mineral oils. As a consequence of this accidental discovery, the retorts were so altered that about 20 per cent. more kerosene oil was obtained than previously. Fig. 1 shows the form of still used for the purpose The retort *A* is of cast-iron, and only the lower part is directly heated. The upper parts are kept superheated (that is, above the distillation temperature) by the flues *B.B.*, *B.B.* The upper part of the retort is uncovered and exposed to the air, so that part of the oil will condense there, and fall back into the strongly heated oil in the retort and down the heated upper portions. In such a retort the oil is distilled until a pitch or asphalt is produced which can be readily run off while hot by the outlet *C*. It should be mentioned that the oil which is obtained by cracking is not of such a high quality as oil obtained in the fractions which are produced before the cracking commences, and, therefore, the uncracked and cracked oils are often collected separately.

At the present day kerosene is not so much required, and is to a certain extent a drug on the market. The most valuable, or at any rate most required, oils are motor spirit, fuel oils and lubricating oils. Motor spirit and lubricating oils require to be highly refined, but with fuel oil this is not necessary. The methods of refining motor spirit and lubricating oils have already been referred to—that is, by treatment with acid and alkali, and, if necessary, subsequent distillation. When, however, the oils contain large quantities of sulphur, the refining is more difficult. Sulphur is objectionable in that it gives the oils a bad smell and colour, and if the oils are to be used for internal-combustion engines a very unpleasant exhaust is obtained.

Canadian oils in particular contain considerable quantities of sulphur compounds, and at one time for this reason they had very little sale. Owing to the unpleasant smell imparted to the oil by the sulphur compounds the oil was known in Canada as "skunk." Special methods of purifying it had, therefore, to be devised.

The oil was first treated with sulphuric acid which, after agitation and settlement, was drawn off. A second treatment with acid followed. After the residue had been drawn off the oil was washed, without agitation, with water. The water was drawn off and caustic soda added, after which the mixture was agitated for about a quarter of an hour. The mixture was allowed to settle and the alkaline layer drawn off. Then the oil was agitated with a further caustic soda in which litharge had been dissolved. The sodium lead salt reacted on a portion of the sulphur compounds,

lead sulphate was produced, and the oil was completely deodorised. It was now necessary to remove the excess of lead, and for this purpose flowers of sulphur was added, the mixture agitated and allowed to settle overnight. Such a process is much more complicated than the ordinary methods of refining, and is not now used. Many other processes have been suggested, such as, for example, (*a*) distilling the oil over lead oxide, and subsequently refining it with sulphuric acid; (*b*) passing the vapours of the oil over heated iron or copper; (*c*) treating the oil with a solution of copper sulphate, caustic soda and common salt, and then digesting it with flowers of sulphur, this doing away with the sulphuric-acid treatment.

It should be mentioned that most oils after being refined are bleached by running them into shallow pans and exposing them to the action of the light. This, of course, could not be done with petrol oils owing to their too great volatility.

For the purification of illuminating oils a new process has recently been introduced by Dr. Edeleanu, in which liquid sulphur dioxide is used in place of sulphuric acid. In illuminating oils, if a clear white flame is to be obtained, the preponderance of the hydrocarbons of the paraffin and naphthene series is of importance. If there are larger quantities of unsaturated hydrocarbons in the oils, the illuminating qualities are reduced. It is, indeed, possible to construct lamps which will give a bright white flame with unsaturated oils; but this would mean that the consumer would have to be in a position to dictate as to the quality of the oil which he was purchasing. Oils from Pennsylvania are most generally used, and these consist in the main of saturated hydrocarbons of the paraffin series. Russian burning oils contain chiefly saturated hydrocarbons, also of the paraffin and naphthene series. Other oils which contain considerable quantities of unsaturated hydrocarbons can be treated with sulphuric acid until the bulk of the unsaturated hydrocarbons is removed; but the loss is great, and the dissolved, or rather decomposed, hydrocarbons cannot be recovered. By the process of Dr. Edeleanu the unsaturated hydrocarbons are indeed dissolved out, but they are not decomposed and lost. Whilst, therefore, the saturated oils are freed from the unsaturated and can be used for illuminating purposes, the unsaturated hydrocarbons can be recovered and employed for other purposes.

The principle of the method is based on the property of liquid sulphur dioxide to dissolve unsaturated and aromatic hydrocarbons rich in carbon more readily than the saturated hydrocarbons of the paraffin and naphthene series. When a petroleum distillate is mixed with liquid sulphur dioxide at a low temperature, two layers are formed. The lower layer consists mainly of the unsaturated hydrocarbons dissolved in liquid sulphur dioxide, while the upper layers contain chiefly saturated hydrocarbons with a small quantity of sulphur dioxide. In practice the best results are obtained at a temperature of 5° C. to 10° C. In order to obtain the most satisfactory results the solvent should not be used in one portion, but in several small portions in succession. In fact, in all cases of extraction better results are obtained by adding the solvent in successive small quantities, rather than all at once.

Unsaturated hydrocarbons have a higher specific gravity than saturated hydrocarbons because they contain a higher proportion of carbon. It naturally follows, therefore, that the specific gravity of oils which have been treated with liquid sulphur dioxide is reduced. This is shown by the following three examples:—

	Original Gravity.	After Treatment.
Tustanowice oil . .	0·8150	0·8040
Mexico	0·8014	0·7901
Peru	0·8042	0·7890

The small amount of sulphur dioxide retained in the upper layer is readily got rid of by evaporation, and the last traces by washing with water.

Oils treated by the sulphur-dioxide method have a lower specific gravity, a lower sulphur content, and a slightly higher flash-point, as shown in the table given on p. 846.

The illuminating power of the oils is increased and the hourly consumption decreased. The specific gravity of the extract, which consists mainly of unsaturated hydrocarbons and aromatic bodies, is considerably higher. The products so obtained have not much value for motor or illuminating purposes, but are said to make a valuable turpentine substitute for the paint and varnish industry because the oil has good drying properties and may be used as a substitute for gums, resins, etc.

Plant dealing with 62 tons per day has already been installed, and Engler considers that it is an important innovation in that it allows the manufacture of illuminating oils from materials which were hitherto considered unrefinable.

Crude Oil from	I. Properties.	II. Crude Distillate.	III. Oil by Usual Methods.	IV. New Method.	V. Lower Layer or Extract.
Bushtenari . .	Specific gravity	0·8200	0·8195	0·8028	0·8650
	Flash-point	80·6°	83·5°	84·5	—
	Sulphur	0·052%	0·016	0·008	0·042
Tustanowice .	Specific gravity	0·8090	0·8084	0·7970	0·8875
	Flash-point	95°	95°	96°	—
Mexico . . .	Specific gravity	0·8030	0·8025	0·7926	0·8640
	Flash-point	78·8°	79·7°	80·6	—
	Sulphur	—	0·404	0·164	1·10
Peru	Specific gravity	0·8175	0·8165	0·8122	0·8630
	Flash-point	73·4	74·3	0·75	

The working of the process technically is illustrated by the following scheme (Fig. 2):—

The crude distillate is passed through the filter (1), where it is filtered through a mixture of salt and calcium chloride to free it from moisture. The dry oil then passes into the tank (2), from where it is pumped into the cooler (3), passing on its way a heat-extractor (4). The liquid sulphur dioxide is passed from the tank (*a*) into the cooler (*b*) and through the pre-heater (*c*). The oil is passed from the cooler into the agitator (5), where the sulphur dioxide is added in the form of a fine spray. Mechanical agitation is thus not required. Two layers are formed, the upper one of kerosene and the lower the unsaturated hydrocarbons and sulphur dioxide. When sufficient sulphur dioxide has been added, which is done in several portions, the lower layer is removed, passed through the heat-extractor (4) and into the evaporator (6). When the whole of the lower layer has been removed, a valve is reversed and the upper layer of kerosene is passed into an evaporator (*d*), passing on its way the heat-extractor (*c*). The sulphur dioxide is removed in the two evaporators (6) and (*d*), the small quantities which remain being easily washed out with water. The bulk of the sulphur dioxide, about 90 per cent., is recovered by passing into a condenser, where it is liquefied and passed back into the tank. The remainder of the sulphur dioxide which is being exhausted from the evaporators (6) and (*d*) is passed through the compressors (*f*) into the condenser (*e*), where it is liquefied and passed into the tank. The Pennsylvania oils are chiefly worked for illuminating

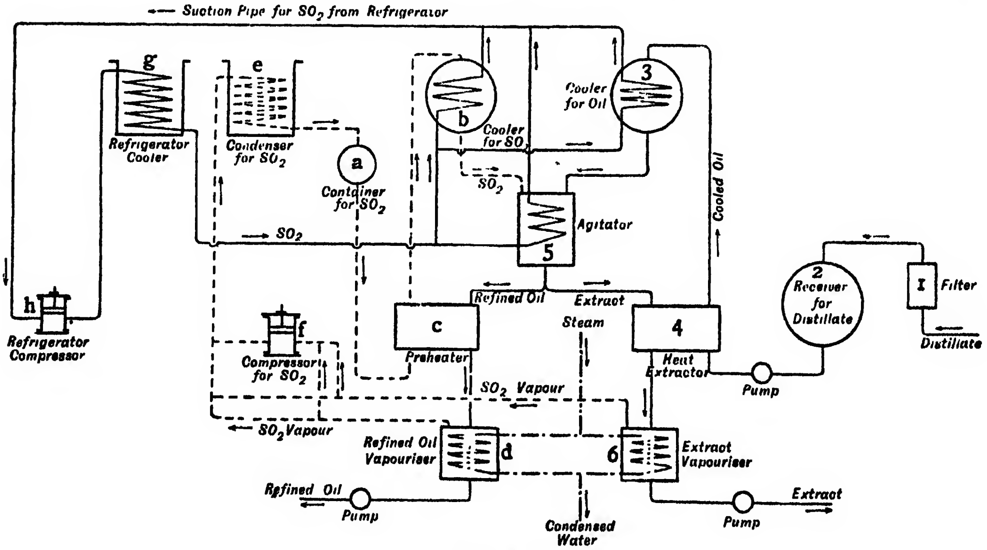

FIG. 2.

oils, whereas the Caucasian yield a very valuable lubricating oil. As already mentioned, lubricating oils are refined with sulphuric acid and alkali in a similar manner to the lower fractions, after which they are placed in clarifying vessels. Sometimes, however, it is found difficult to remove the colour by ordinary methods of refining, and they are filtered through bone-black or the charcoal residue obtained from the manufacture of potassium ferrocyanide, which is a particularly active form of carbon. *Vaseline*, a non-crystalline semi-solid oil, is obtained from the higher fractions of American oils, and was first placed on the market by the Cheeseborough Manufacturing Company. Certain crude petroleums are distilled in vacuum in order to minimise dissociation, and the semi-solid products filtered hot through granular animal charcoal or Fuller's earth. The first runnings are colourless and are collected separately. Certain forms of infusorial earth are also sometimes used. Vaseline can also be obtained from Russian and Galician oils.

Vaseline is largely employed in pharmacy for making ointments. It often has antiseptics mixed with it, such as salicylic acid, boric acid, camphor, etc. A product put on the market by the Cheeseborough Manufacturing Company, which is composed of vaseline and camphor, is known as camphor ice. Vaseline is also employed as a lubricant, and for smearing on metal articles to prevent corrosion.

Specially purified odourless and tasteless petroleum is now largely used medicinally, and is sold under the name of *Paraffinum Liquidum*. This product is best prepared from Galician lubricating oil or Russian distillate having a specific gravity of 0·890 to 0·905, or a mixture of vaseline oil and lubricating oil. The oils are first treated with ordinary sulphuric acid to remove any moisture and then with fuming acid. After this treatment the tarry residue is run off, and the oil again treated with ordinary sulphuric acid to remove sulphonated bodies which may be dissolved in the oil. The residual oil is then washed with water and alkali, and may finally be treated with alcohol which is evaporated off, and the oil filtered through charcoal or Fuller's earth. The final specific gravity of the oil is 0·880 to 0·885. The process is difficult, owing to the emulsifying of the very viscous oil with the water and alkali solution. It is interesting to note that although the specific gravity is decreased by the treatment, the viscosity increases. American oils are much more difficult to refine in this manner owing, it is said, to the larger amount of sulphur contained in them; but I understand that white petroleum has now been produced successfully from certain oils of American origin. This is a very important matter, because, while the war lasts, it is impossible to obtain oil from the continent of Europe. My own opinion is that Russian oils are more readily purified in this manner owing to their high content of naphthenes.

It frequently happens that the higher fractions of petroleum are semi-solid owing to being a mixture of lubricating oil and crystalline paraffin. Amorphous semi-solid vaseline is a good lubricant, but the admixture of crystalline solid paraffin reduces the viscosity of the oil, and must, therefore, be removed if the oil is to be used as a lubricant.

In the United States the residue remaining after the distillation of the kerosene fraction, which has a specific gravity of about 0·940, is distilled in a current of superheated steam from large cylindrical steel stills. The steam prevents decomposition and cracking of the hydrocarbons, which would decrease the yield of solid paraffin and lower the viscosity of the lubricating oil. The water surrounding the cooling pipes is kept warm to prevent the solidification of the paraffin wax.

The first fraction which passes over has a specific gravity of about 0·834, and is frequently re-distilled with a second charge. The residue is generally distilled in two fractions, the proportions of which vary with the description of the oil required. The specific gravity of the second fraction usually varies between 0·860 and 0·870. The specific gravity of the final fraction varies between 0·910 and 0·922. Each fraction may be divided into several further fractions to produce different classes of lubricating oils.

The oil is purified in the usual manner with sulphuric acid and caustic soda, the temperature being kept sufficiently high to prevent solidification of the paraffin wax. The purified oil is then passed through the cooled pipes. As it cools the solid paraffin separates out, a semi-solid mass being obtained. This semi-solid product is then passed through filter presses which remove the bulk of the oil. The cake is then subjected to hydraulic pressure, which removes a further quantity of oil, and then "sweated." This is a process of fractional fusion which removes the lower melting wax and any remaining oil.

The paraffin cake so obtained still has a

yellowish tint, and requires to be further refined in order to make it perfectly white. The final refining consists in mixing it with charcoal in a steam-jacketed pan. The charcoal is intimately incorporated with the melted paraffin by means of a current of hot air, after which the mixture is filtered, the charcoal remaining behind and the decolourised paraffin passing through the filter. The paraffin is then allowed to cool, when a solid white product is obtained.

The mineral-oil industry is one of the largest industries of the world—perhaps the largest individual industry. The total world's production to-day is about 50,000,000 tons per annum, and prospectors are feverishly engaged in trying to find more. The evolution of the industry has been a gradual one. When the first gusher was struck in 1859 the chief use for the oil was as an illuminant in place of the vegetable and animal oils previously employed. Then by degrees it was found that the higher fractions contained valuable lubricating oils and paraffin wax, which is the basis of most of the candles employed at the present time. Pure paraffin wax is not satisfactory for the candle industry, as it is too soft and the candles are apt to bend. Small quantities of stearine are, therefore, usually added to it. In connection with the candle industry, it is interesting to note that when pure paraffin wax is used it is difficult to colour the candles, as most dyes do not colour paraffin. By employing a mixture of stearine or other animal or vegetable wax the dye is readily taken up.

Again a change has come over the mineral-oil industry. With the introduction of the internal-combustion engine for motor-cars, stationary motor-engines, aeroplanes, etc., the requirements of the lower fractions which constitute petrol have enormously increased. Twenty years ago the lower fractions were a drug on the market. To-day kerosene is the drug, and the lower fractions and the fractions above kerosene, which are used for fuel oil for heavier engines of the Diesel and semi-Diesel type and as a fuel for direct firing, are what is required. The requirements for lubricating oil are always increasing.

THE TRADE OF FOOCHOW.

Some interesting information is given by H.M. Consul at Foochow on the trade of that district in 1914.

That the hostilities in Europe have had a detrimental effect on the foreign import trade of Foochow is obvious from the returns for 1914, which show a falling-off under almost every heading. The decline is due to the rise in the price of all foreign articles, the silver cost of which, as a result mainly of the fall in exchange, has risen at least 10 per cent. since August, while certain articles supplied by Germany and other European countries have more than doubled in cost. Business was also affected by the stoppage during August and part of September of the foreign export trade, which, while it lasted, caused great anxiety to the mercantile community and restricted all commercial operations.

Capture of Enemy Trade.

The chief imports into the Foochow district of German origin have been aniline dyes, artificial indigo, needles, Berlin wool, hosiery, blankets, silk bordering for Chinese dresses, lampware, and umbrella frames, while Belgium has supplied glass, and Austria-Hungary enamelled ware. Though in no single item is the trade of any great importance, yet its aggregate value is considerable. Since the war commenced all the articles mentioned have risen greatly in price, but so far it is only in aniline dyes, indigo, and glass that the scarcity has been seriously felt. Dyes and indigo in particular have become indispensable to the Chinese, and, unfortunately for them, Germany is the only present source of supply. For the trade in umbrella frames and that in enamelled ware, Japan is making a strong bid, and will, no doubt, capture both, and probably the trades in lampware and hosiery also—in all of which articles cheapness is more essential than quality. There seems no reason why British firms should not supply the needles and blankets hitherto imported from Germany, or the better qualities of window and mirror glass formerly supplied by Belgium.

There were heavy increases in 1914 in the imports of American and Sumatra oil and a decline in imports of Borneo oil; but the most interesting feature of the year in connection with the oil trade is the appearance on the local market for the first time of Japanese oil. Judging from the number of complaints made to the Foochow Consulate, this oil, which is mostly of very poor quality and correspondingly cheap, is purchased by Chinese dealers, either to be surreptitiously mixed with the more expensive American and Sumatra oils or to be sold as such to ignorant customers, who are easily deceived by the likeness in the labels.

Except in such articles as kerosene and other oils there is little or no direct import trade between Foochow and foreign countries, local dealers preferring to purchase their stocks of other goods in Hong-Kong and Shanghai.

Cotton Goods.

In the report on the trade of the port for 1913 the total value of the native cotton goods imported into Foochow that year was placed at 1,319,807 taels* and that of the foreign cottons at 1,419,106

* The average value of the Haikwan tael in 1913 was 3s. 0¼d., and in 1914 2s. 8¾d.

taels. It was also pointed out that, in view of the increasing supply of cotton yarn and cloth from the Shanghai mills, it seemed likely that the small percentage in favour of the foreign products would soon disappear. The rise in 1914 in the cost of foreign goods has brought about this change rather sooner than might have been expected. Whereas the import of foreign cottons in 1914 has declined in value to 1,218,474 taels, that of native cottons, in spite of a lower valuation by the Customs, has increased to 1,413,739 taels. The decrease in the foreign import is mainly accounted for by smaller purchases of Indian yarn, with which, at its present price, the Shanghai article is able, it would seem, to compete on equal terms. The piece-goods trade, in which there is no native competition with the finer classes of goods, has been less affected, but until exchange improves again the foreign trade is bound to languish.

A Backward Province.

An exhibition of provincial exhibits for the World's Fair at San Francisco was held in Foochow during the summer, but the display was not a creditable one for a province of the size and population of Fuhkien, the industrial backwardness of which could hardly have been more clearly demonstrated. The province is still without roads or railways, or any industries other than two wood-sawing mills, for which the use of machinery is essential, and though possessed of considerable mineral resources no attempt is being made to develop them. The poverty of the people is to some extent accountable for this state of things, but the conservatism and lack of enterprise of the native business men is the chief obstacle in the way of progress. The Fuhkienese are also possessed with a somewhat exaggerated idea of the importance of their province and of the temptation it offers for foreign aggression, which they still believe can only be resisted by rejecting all offers of assistance in developing its resources. Until they wake up to the danger of this policy, there is little likelihood of any improvement in the trade of the Foochow Consular district and any consequent expansion in the market it offers for foreign goods. For the benefit of British manufacturers who send motor-car and similar catalogues to the Consulate at Foochow, it may be mentioned that, owing to the total absence of roads referred to above, there can be no wheeled vehicles in use in the district. Transport is by boat wherever rivers, with which Fuhkien is fortunately well supplied, are available, or, where water carriage is impossible, by pack bearer. Animals are hardly used at all, human labour being cheaper.

TREND OF INVENTION IN 1914.*

The subject of locomotion in general maintains its pre-eminence in the field of invention. The flow of applications relating to the many branches of this subject was maintained at about the same rate as in the previous year until the outbreak of war, after which a considerable fall took place.

The great activity noted during the last few years in the motor-vehicle industry appears to have passed its zenith, the number of applications in connection with motor-vehicles and internal-combustion engines, although still great, showing a notable falling-off as compared with the previous year's total. Considerable attention has been given to the cycle type of vehicle, including motor attachments of the "auto-wheel" type to cycles. Tractors for agricultural and military purposes, and signals for indicating to a following vehicle an intention to turn or stop, are also noteworthy features.

The interest in railway signalling has been well maintained, but no marked departures from known types of apparatus are revealed. As a further instance of the interest taken in the safety of railway passengers, a great amount of inventive ingenuity has been applied to the problem of simultaneously locking all the carriage doors of a train from the guard's van.

The outbreak of war naturally provided a stimulus to inventions connected with military and naval subjects, particularly aerial warfare and submarine mining. Bombs and their projection from aircraft have claimed considerable attention from inventors, as also have means for detecting submarines and torpedoes, and for protecting ships therefrom.

Applications for darts, mechanical means for throwing bombs and other projectiles, and body-armour provide an interesting sidelight on the revival of ancient methods of warfare.

Amongst other inventions in connection with military matters may be mentioned bullet-proof shields; periscopes for enabling observations to be made while the observer remains under cover in a trench; sleeping-bags; and combination knives, forks, and spoons.

The issue of Treasury notes of small denomination was the occasion of a considerable number of applications for purses for holding paper currency.

Toys and games, particularly of a warlike nature, are responsible for a large number of applications. Dolls' heads and eyes, previously largely made abroad, and "foot-cycles," now so popular amongst the juvenile section of the community, may also be worthy of mention in this connection.

The disaster to the submarine A 7 directed attention to the problem of locating wrecked submarines, and signalling to and rescuing their occupants.

In the field of aeronautics, in which invention has been very active during the last few years, a marked falling-off is observed.

The interest in visual signal-indicators for mines has been well maintained.

The electrical industry as a whole is very prominent, although few outstanding features call for comment. There has been continued progress

* From the last Report of the Comptroller-General of Patents.

in automatic and semi-automatic telephone systems. Attention has also been given to receiving-arrangements for cable telegraphy, and to ionized-gas relays for use in telephony and wireless receivers.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Technical Progress.—It is probable that technical progress is more active than could be supposed from the signs upon the surface of affairs. The noticeable dearth of novelties in machinery, processes and goods does not imply that effort and ingenuity have been paralysed. Energies have been diverted, sometimes to the acquisition of forgotten knowledge or to the practice of expedients which are unfamiliar without being new. Most manufacturers have had to make essays in doing without one or another of the things that are ordinarily deemed indispensable, and if the results of these experiments are not showy there is no cause to regard the efforts as wasted. The textile art is essentially one of peace, and war conditions do not help to further it as a whole. One of the broad effects of war has been to promote the production of the plainer classes of goods. For one thing such textiles as are wanted for direct military purposes are distinctly plain; for another the interruptions and uncertainties of war have interfered in every way with the normally lengthy processes of preparing and marketing new goods of a fancy description. As often as possible the old patterns are made to serve again, and all avoidable complexities in any new goods that are introduced are instinctively shunned.

Dyed Goods.—The inadequacy of the dyestuff supply accounts fully for the limitation of fancy effects obtained by the use of colour. Only a select number of colours are available at all, and responsibility for exact matching is altogether disclaimed by the dyers. The difficulty is not with sober blacks, blues and browns, which can be dyed passably well in unlimited quantity, but with the fine, bright and delicate shades wanted to enliven deader colours in the dye-vessel, or for contrast or for bright-hued garments. Very bright, very fast and very level-dyeing colours are scarce, are increasing in scarcity, and are those which dyers in the present most want. Dyers do their best with such materials as they can encompass, but it is scarcely their opinion that all the work they are driven to turn out will yield satisfaction to the ultimate consumer. Some of them live in open expectation of trouble to follow. It does not appear that sellers of goods have made the most of their opportunity to press the sale of fast-dyed cloths. The fact that goods were dyed a year ago instead of a month ago does not mean universally that the colours can be relied on to withstand sunlight and wear, but the presumption is in their favour. It is prudent meanwhile to distrust all bright and delicate shades and to prefer such as were dyed when the choice of materials was abundant.

Conditions in Germany.—The pains taken to conceal the industrial situation in Germany fail at any rate to disguise the fact that the plight of textile operatives in that country is much worse than here. According to information from Geneva, the Concordia Spinning Mills of Bunzlau have their people working for twopence an hour—9·51 marks for 57½ hours. The particulars are taken from tickets which upon the obverse caution the workers to be economical in their use of bread. The internal evidence suggests that the tickets have been issued to women workers. In Saxon Thuringia the weaving manufacturers not long ago conceded war bonuses to their workpeople at the rate of threepence a day to married men and half as much to women and unmarried males. It was provided that in any case married men should not receive more than 22*s.* a week, unmarried men not more than 18*s.*, married women not more than 16*s.*, or unmarried more than 12*s.* Food is reported considerably dearer than in England, and there are several things to show that the German mills are not making anything like the usual six days per week. Some of the finishing works have been employed only two to three days for a considerable while. In Socialist quarters it has been apprehended that 30,000 men in Chemnitz would be thrown out of work by the recent restrictions upon the use of cotton. A safe inference is that there is material want and suffering. More than half the operatives of some mills are with the German army. Approximately half the regular trade of the country has been cut away by the stoppage of exporting, and the prices of materials show the difficulties of importing. Raw cotton in Bremen costs about six times as much as in Liverpool, and in Austria the authorities have lately fixed maximum prices for home-grown wools representing from two to four times the high prices ruling in England. The Austrians, however, have liberty to pay dearer for any imported wool that they can get.

The Labour Supply.—The repair departments of textile mills have been yielding both their men and their machinery for the manufacture of munitions, and the absences are bound to make themselves felt increasingly as small repairs fall due. The cotton-weaving employers in Lancashire, to facilitate recruitment and the making of munitions, have agreed to reinstate all workpeople who may enter the Government service. A similar understanding may be expected in other important cases. A certain number of textile mills were until a fairly recent date employed mainly or fully upon direct or indirect Government work, and while such was the case it was realised by all that their men could not be spared for the ranks. Now that there is a lull in official contract work some of those people have become presumably eligible. However, it is to be believed that large contracts

will come again, and in these circumstances an employer feels an intelligible reluctance to part with his staff. The difficulty is one that should give way to organisation, and the data elicited by the National Register are likely to secure full attention to it. The worst fears of the unreasonableness of officials have not been realised as yet, and in proceeding by conferences, in which employers, employed, and the officials participate, there is every promise of a mutual understanding.

The Bishop Blaize.—There are "Bishop Blaize" inns in two or three of the towns in which woolcombing is at present done. A century ago Bishop Blaize processions formed a regular feature of the wool-combers' year, and the effigies of the Bishop upon tokens and handbills show him as patron saint of the combing trade. It does not appear, however, that he, like the father of Columbus and some other distinguished persons, worked at the craft. The combers have not even a monopoly of his patronage, for at various times and places he has been the saint also of weavers, builders and masons, the patron equally of swine and the great protector against wild animals and throat complaints. His association with combing arose out of the probably erroneous supposition that he was done to death with woolcombs instead of with the *ungulae* or hooks forming the common instrument of torture in Roman times. The probabilities have been examined in a notably able paper given to the Society of Antiquaries by Mr. H. Ling Roth, and now republished in Bankfield Museum Notes (Halifax: King, 2*s.* 8*d.*). The author's conclusion is that Blaize and woolcombing became associated first between the tenth and twelfth centuries. About the end of the eighteenth century Blaize was in the zenith of his fame among the craft in England. The cruel impoverishment of combers at the time of the advent of machinery might account for the disappearance of the rites of celebration; but if little honour is paid nowadays to the martyr he yet remains the traditional saint of the trade. Custom seems to appoint February 3rd as the date of commemoration.

Cotton as Contraband.—Members of the cotton trade are not nearly so enthusiastic as some others in urging the inclusion of raw cotton in the British list of contraband. The closer one is drawn to the trade, the more one recognises complexities not clearly apparent from a distance. There are no two opinions about the necessity for withholding cotton from the enemy. The belief is widely held that to declare cotton contraband would not make its supply to the enemy more difficult than at present, and would intensify the dissatisfaction of neutral nations whose goodwill is of some moment. The delicate points in the present situation are appreciated as keenly by cotton traders as by anybody; and, perhaps rather more than most people, they realise their responsibilities towards the future. It is important to remember that cotton can in no case be raised in this country, and that there may be future wars, fought in different conditions, when a precedent set now for the sake of a doubtful advantage might be used to the grave detriment of a large part of the industrial population. The considerations are weighty enough to deter spinners from joining uncritically in a popular cry raised—as they believe—by persons of less responsibility and understanding than themselves. There are no discoverable objections against making cotton contraband providing that the step is taken after the fullest consideration.

British Wool.—The idea that the war has still a long course to run is emboldening buyers of the British wool clip to pay higher prices than the market immediately warrants. The advance upon last year's prices is about 50 per cent., at which it is possible that some varieties represent a better speculation than others. There seems to be more prospect of large new contracts for hosiery than for army cloth, so that the Downs or shorter wools are favourites. Last autumn quantities of long British wool were used in the absence of a sufficiency of New Zealand crossbred, of which the supply this year is more abundant. There is no invariable rule to that effect, but Nature is often merciful in years of high prices, and wool merchants are free to admit that this year the fleeces are uncommonly thrifty. The unwashed wools from some districts are computed to yield fully 5 per cent. better than the average. The comparative absence of grease and moisture is much more than offset by the enhanced price, but the small advantage is gratefully received by the buyers. The height of prices and the restriction of bank credits limit the ability to buy speculatively, and financial influences are perhaps destined to become still more effective in curtailing the advance of quotations.

CORRESPONDENCE.

MUNITION METALS.

I have noted the summary (contained in the *Journal* of July 23rd) of Professor H. C. H. Carpenter's contribution on the above subject to *Nature*. With reference to zinc and antimony, the latter having reference to China, I wish to say that if zinc can be handled in furnaces here at home it can be bought in very large quantities in Bolivia and shipped from the mine and landed in England within twenty-four days. Antimony can be bought at Uyuni, Bolivia, for £4 per ton of high-grade ore. The British Vice-Consul at Uyuni is in an excellent position to advise on output, prices, etc., of these and other munition metals.

The writer has just returned from Bolivia, and is desirous to have British manufacturers know where munition metals, such as copper, lead, zinc, antimony, etc., can be obtained quickly. Regular steamship service is maintained to and from the west coast (South American) ports.

Burnley, Lancashire, July 24th, 1915. WILLIAM T. TAYLOR.

GENERAL NOTES.

THE GERMAN AMBER INDUSTRY.—The harvest of amber on the German shore of the Baltic Sea was very satisfactory in 1914. According to reports of the Prussian Government, which holds the monopoly of the entire German amber production, the output last year reached 800,000 carloads of 1,100 lb. each of alluvial wash containing amber, each carload netting 1·2 lb. of raw amber. The output of the works amounted to 478 metric tons (of 2,204·6 lb.) of raw amber, 28 metric tons of pressed amber, 236 metric tons of molten amber, 4 metric tons of succinic acid ($C_4H_6O_4$), and 55 metric tons of amber oil, the aggregate value being £250,000. The net earnings of the works, which employ about 1,500 men, amounted to £35,000. In view of the increased demand for amber, the output does not keep up with the demand, although the works are running full time.

ORIGIN OF PETROLEUM. — The long-debated question as to the origin of deposits of petroleum, is dealt with by the investigations of M. Jean Chautard, the result of which was recently presented to the French Academy of Science. According to this gentleman's researches in different parts of the globe, the petroleum-bearing rocks never present characteristics denoting an igneous origin. They are invariably sedimentary rocks, and, moreover, they all contain deposits which indicate alternations of marine and lagunary conditions. Such alternations are, of course, the sign of intermittent regressions of the waters covering them. "This fact," according to the *Bibliothèque Universelle* of Lausanne, "enables us to form an idea of the conditions favouring the formation of petroleum. During the lagunary periods there was an accumulation of organic *débris*, the remains of animals and vegetables which had either lived or died there. The marine recurrences brought impermeable sediments which covered the *débris* and protected them from the oxidizing action of the air, thus permitting them to become bituminous. Hence petroleum would appear to be of organic origin and not mineral.

FOREIGN TRADE OF JAPAN.—The latest statistics of the foreign trade of Japan, covering May and the five months to the end of that month, reveal a fairly substantial decline as compared with the corresponding periods last year. The total value of exports during the month amounted to £5,114,100, against £5,391,700, while imports amounted to £5,741,900, against £6,156,500. The aggregate value of the month's trade was, therefore, £10,856,000, in comparison with £11,548,200 in May, 1914, and showing an excess of imports of £627,800, against £764,800. Exports for the five months reached a value of £24,545,700, showing a decrease of £1,849,900 when compared with the first five months of 1914. Imports at £24,459,200 exhibit a much greater drop of £7,322,000, so that the total trade for that period was some £9,171,800 down at £49,050,000. There was an excess of exports over the five months of £86,500.

ELECTRIC MACHINERY IN CHINA.—H.M. Consul-General at Shanghai reports that the importation of machinery and the installation of electric-lighting apparatus in China is worthy of the closest study by British firms who are interested in the machinery market. China shows a vigorous and increasing demand for electricity in all its branches. The Shanghai Municipal Electricity Works supplied over 40,000,000 units during 1914, as compared with 21,000,000 units in the previous year; 1,500 radiators have been installed in Chinese houses, and small motors are very popular. The installation of plant in the interior requires special measures, and cannot be attempted without efficient local representation. The business was largely in the hands of German firms, mainly because they were willing to undertake entire contracts and to finance them. British firms, however, have realised the possibilities of the market, and those who have been sufficiently enterprising to meet the local conditions are being amply repaid for their trouble, whilst their work has given the greatest possible satisfaction to the Chinese companies on whose behalf contracts have been undertaken. British installations have recently been completed for the great cities of Soochow, Changchow, and Yangchow, in the Province of Kiangsu, and for Ningpo, in the Province of Chehkiang, whilst a very large number of smaller plants and dynamos have been supplied for lighting small towns, missions, and factories.

SWISS POSTAL STATISTICS IN WAR TIME.—The following statistics, issued by the Federal post office in Switzerland, give some idea of the magnitude of the work imposed upon that department by the existing war conditions. During the month of May no fewer than 2,084,175 letters or post-cards, 215,530 small packets, and 976,649 packages by parcels post, addressed to French prisoners in Germany, passed through the Swiss post office, whilst the mail forwarded to the German prisoners in France comprised 2,944,775 letters or post-cards, 55,255 packets by letter, and 77,083 by parcels post. In addition, 52,772 post-office orders, representing a value of 1,748,535 francs (£69,742), were issued for French prisoners in Germany, and 24,917 orders, to the value of 415,441 francs (£16,617), were issued for German prisoners in France. During the same month, the amount of mail handled daily by the Swiss post office for the benefit of the prisoners of war averaged 162,224 letters and post-cards, 8,735 small packets, and 33,991 packages by parcels post. An average of 6,656 post-office orders, to the value of 92,424 francs (£3,697), were issued daily. The total number of parcels sent by post since September, 1914, to end of May, 1915, was 2,625,179 to French prisoners in Germany, and 565,097 to German prisoners in France.

Journal of the Royal Society of Arts.

No. 3,274. VOL. LXIII.

FRIDAY, AUGUST 20, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

PETER LE NEVE FOSTER PRIZE.

Mr. Reginald Le Neve Foster has presented the Society with a donation of £140 for the purpose of founding a prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879.

The Council have determined to offer the prize for a paper on "Zinc, its Production and Industrial Applications."

The prize will consist of a sum of £10 and the Society's Silver Medal.

The paper for which the prize is awarded will be read at one of the Ordinary Meetings of the Society.

It is expected that some account will be given of the history of the metal, the sources of its supply, its metallurgy, and the various uses to which it has been, or may be, applied.

Intending competitors should send in their papers not later than December 31st, 1915, to the Secretary of the Royal Society of Arts, Adelphi, London, W.C.

The paper must be type-written. It may be sent in under the author's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges nothing deserving the full award is sent in.

FOTHERGILL LECTURES ON "MOTOR FUELS."

The Fothergill Lectures on "Motor Fuels," by Professor Vivian B. Lewes, F.I.C., F.C.S., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

OILS, THEIR PRODUCTION AND MANUFACTURE.

By F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.T.

Lecture II.—Delivered January 25th, 1915.

The shale-oil industry is one of great importance to Scotland, and in these days of depreciating British method and British enterprise may be pointed to as a triumph of engineering and chemical skill over very great difficulties. That an industry dependent upon the distillation of shale, from which, on the average, only 23 gallons of crude oil per ton are obtained, has been able to hold its position against the enormous competition of oil obtained from the oil-fields is, indeed, something to be proud of, and it has only been done by strictest attention to detail and continual improvement in method.

The shale-oil industry in this country was founded by Dr. James Young, who was manager of a chemical works in Liverpool. In 1847 Dr. Lyon Playfair—who afterwards became Lord Playfair—drew Dr. Young's attention to a small stream of oil which flowed from some coal workings at Alfreton in Derbyshire. From this oil Young succeeded in abstracting, on a commercial scale, wax and burning oil and a heavy lubricating oil. As, however, the supply of raw oil soon became exhausted, Dr. Young, believing the oil to have been produced by low temperature distillation of coal by terrestrial heat, endeavoured to obtain oil by slow distillation of coal in retorts. He experimented with a large number of English and Scottish coals, and finally found that the Torbanehill or Boghead coal in West Lothian yielded from 120 to 130 gallons of oil per ton of coal distilled. In 1850 Young took out a patent for "obtaining paraffin oil, or an oil containing paraffin, from bituminous

coal." By the end of the same year the Bathgate Oil Works were started under the name of Young, Meldrum and Binny. The Torbanehill deposits were worked for about twelve years, when they became exhausted, and since that time the Scottish shales of Linlithgow and Midlothian have been the principal source of supply.

It is interesting to note that Young's process was largely worked in America until the advent of natural oil in 1859 and the accompanying oil fever. Oil shale is dark grey or black in colour, and usually has a laminated or horny fracture. Shales do not coke when heated, and, as the mineral content is very high—generally over 70 per cent.—the spent shale is practically of no use, as is evidenced by the huge dump heaps which are to be seen at the shale-oil works, and are by no means beautifying to the landscape.

The quantity of oil and of sulphate of ammonia yielded by shales varies considerably. It may be as high as 30 to 40 gallons per ton of shale, but is sometimes as low as 17 to 18 gallons. The original shales worked by Young yielded from 40 to 45 gallons per ton, and with present-day methods of retorting would undoubtedly have yielded more. The average yield in Scotland to-day is, however, only 23 gallons per ton. The amount of sulphate of ammonia yielded depends largely upon the percentage of nitrogen in the original shale.

Young's patent expired in 1864, and this led to a great expansion in the Scottish oil industry; but shortly afterwards, owing to the output of natural oil and the American competition, it experienced a severe check. The discovery in 1859 by E. L. Drake of oil wells in Pennsylvania was followed by the importation into England of lamp oils. In the early days of the shale-oil industry lamp oil was the principal product, and during the run of Young's patent fetched about 2*s.* 6*d.* per gallon. After the expiry of the patent it fell owing to competition to 1*s.* 6*d.*, and when the American oil came on to the market the price dropped much lower, until to-day illuminating oil can be obtained for about 5*d.* per gallon, and the price has even been lower.*

At first the Americans exported chiefly illuminating oils, but after a time they supplied lubricating oils and solid paraffin. In 1871 there were fifty-one oil works in Scotland, which produced about 25,000,000 gallons of crude oil. As the American competition increased, the smaller works gradually fell out and the larger works increased in size. Mechanical and labour-saving arrangements were devised, the retorts were improved, purer oil was produced, and the chemicals used in refining were as far as possible recovered. About this time the supply of Peruvian guano began to fail, and, as a consequence, the price of sulphate of ammonia began to increase. In 1880 the price of sulphate of ammonia was £22 to £24 per ton. In 1890 it had dropped to less than £8 per ton, and illuminating oil did not fetch more than 6*d.* per gallon. Further concentration of the works took place. The retorts were specially constructed to give the maximum yield of sulphate of ammonia, and improvements were introduced to produce greater economy throughout the works. With the older retorts not more than 16 lb. of sulphate of ammonia was produced per ton of shale. With the new retorts 35 lb., and even 75 lb., of sulphate of ammonia is obtained per ton, depending, of course, upon the quality of the shale. With the older type of retort it was necessary to produce 30 gallons of oil per ton for the working to be profitable; with the new retorts 20 gallons is profitable. Since 1873 the Russian petroleum industry has developed, and the competition from this source has of recent years been very severe. As, however, paraffin wax is not produced from Russian crude oil they could not compete in this direction, and the manufacture of paraffin wax has always been a profitable undertaking.

One of the chief reasons why the Scottish oil companies have been able to hold their own is healthy rivalry and mutual helpfulness. This has resulted in concentration, and now there are only seven companies, three of which produce only crude oil. Although there are fewer companies (in 1894 there were thirteen), the output of oil and of sulphate of ammonia has increased instead of, as might have been supposed, decreased.

The amount of shale treated in the retorts is over 3,000,000 tons per annum, which produces about 275,000 tons of crude oil, or over 70,000,000 gallons. The marketable products produced by the distillation and refining of the crude oil and their approximate yields are:—

Motor spirit	600,000 gallons.
Naphtha	4,400,000 „
Burning oil	20,000,000 „
Gas or fuel oils . . .	12,000,000 „
Lubricating oils . . .	10,000,000 „
Paraffin wax	25,000 tons.
Sulphate of ammonia .	55,000 „

The total value of the products exceeds £2,000,000 per annum.

* Owing to the war, prices are at present much higher.

METHOD OF MANUFACTURE.

The shale is mined and brought to the surface in hutches. Where necessary it is blasted down by gunpowder. Fig. 3 shows an electric drill which is used to bore the blast-holes. Before being brought to the surface the shale is passed over a 1-in. riddle, all the smalls being left behind in the mine. After being brought to the surface the shale is passed through a breaker, where it is broken into pieces about 6 in. square. It is then discharged into iron tubs, which are run along rails and discharged into the retorts. Fig. 4 illustrates the Bryson retort used at the Pumpherston Oil Companies works. It is long and narrow. There is an iron table below for supporting the shale, and a revolving arm to cause the shale to move downwards.

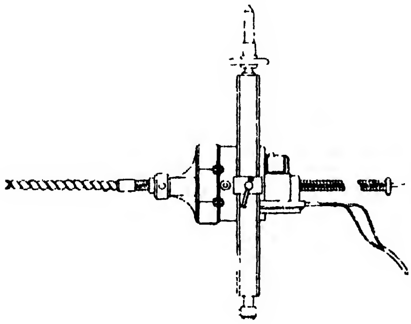

FIG. 3.

Through the centre of the table a steel spindle or shaft projects, on the upper end of which is a curved arm, and this, when rotated, pushes some of the shale off, causing it to fall over the edge of the table into the hopper below. The shaft carrying the curved arm passes through a stuffing-box on the hopper, and has a ratchet and lever fitted to the lower end actuated by a bar or rod of T-iron, which is made to travel horizontally and is driven by gearing from a small electric motor. The motion is comparatively slow, the arm making only one revolution in twenty minutes, and the action is most satisfactory, the throughput of shale being regulated at will. The upper portion of the retort is of cast-iron, 11 ft. long by 2 ft. in diameter at the top, enlarged to 2 ft. 4 in. at the bottom. The lower part is built of firebrick and is about 20 ft. long enlarged to 3 ft. at the bottom. Heat is applied externally from uncondensable gases obtained from the distillation of the shale (assisted, in the case of the poorer qualities of shale, by producer gas), and is made to circulate round the retort by chequers. The heating gas enters near the bottom of the brick portion of the retort, along with a certain quantity of air, and a high temperature (650° C. to 900° C.) is maintained in this portion, where the nitrogen of the shale is converted into ammonia, which is aided by a continuous supply of steam delivered at a slight pressure into the bottom of the hopper. The oil vapours and gases are distilled from the shale in the cast-iron portion at a temperature of about 500° C., and, along with the ammonia gas, are drawn off by the exhausters, at a branch pipe at the top of the cast-iron retort, through the atmospheric condensers. The condensed liquid oil and water containing ammonia flows into a small separating tank. The gases then pass through ammonia scrubbers in which they are "washed" for ammonia, then through the naphtha scrubbers, where the lighter gases, which could not be caught in the atmospheric condensers, are scrubbed with oil, and a good quality of light oil or naphtha is recovered. The uncondensable portion passing from these scrubbers is burned under the retorts. Shales of average quality yield sufficient gas, not only to heat the retort, but also to burn under the steam boilers.

The ammonia water got from the atmospheric condensers is pumped through a heater, in which

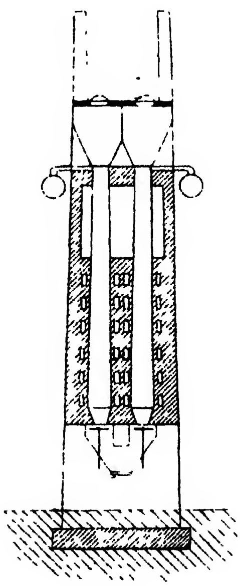

FIG. 4.

it is raised in temperature by the spent or waste water flowing from the still, and passes into the top of the still, which is circular in shape, about

30 ft. high, and has a series of cast-iron shelves fixed horizontally every 2 ft. or thereby from the top to near the bottom. Steam is injected into the bottom of the still, and passes to the top carrying with it the volatile ammonia, while the water, after traversing the whole area of each tray, passes down by a seal-pipe from one to the other, and flows out at the bottom as spent water into a concrete tank containing a cast-iron worm, which acts as a preheater for the ammonia water on its way to the still. During its progress from the top to the bottom of the still, the water is diverted into a chamber containing milk-of-lime, which sets free the fixed ammonia.

The ammonia as it is liberated from the still is passed into a lead-lined saturator containing sulphuric acid, where it is converted into sulphate of ammonia. As showing the care which is exercised to prevent waste, the exhaust steam and waste gases from the saturator are passed into the retorts and utilised to aid in the formation of ammonia from the shale.

Refining the Oils.

The oil as condensed in the coolers is a black, semi-solid liquid. It is pumped into overhead tanks, which are so arranged that the stills can be fed by gravitation. Before being run into the still, the oil is allowed to settle from twelve to eighteen hours, being kept sufficiently warm for it to remain quite fluid, so that the water may the more readily settle. The oil is then fed into the centre still of a battery of oil boilers (Fig. 5). The lightest fraction of oil which consists after purification of naphtha and illuminating oil is distilled off in the first boiler. The stills on each side of the feed-vessels are fed with oil by means of a pipe passing to the bottom of the first still, the heavier oil passing in a similar manner to

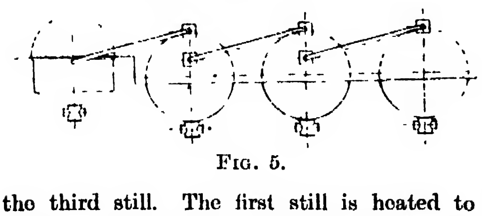

Fig. 5.

the third still. The first still is heated to a temperature sufficient to distil off the light oil, the second to a higher temperature to distil off the fuel oil, and the third to take off the lubricating oil. Thus, fractions of different specific gravity are collected. After the third fraction has been taken off, the heavy oil is delivered into a cast-iron pot-still, where it is distilled to dryness, and a residue of oil coke is left behind. This oil coke is valuable for making electrodes, as it is a fine form of carbon and contains very little ash. At all stages of distillation steam is let into the retorts to aid the distillation and to prevent decomposition.

Condensers.

The various fractions of oil are treated separately with sulphuric acid and soda, and

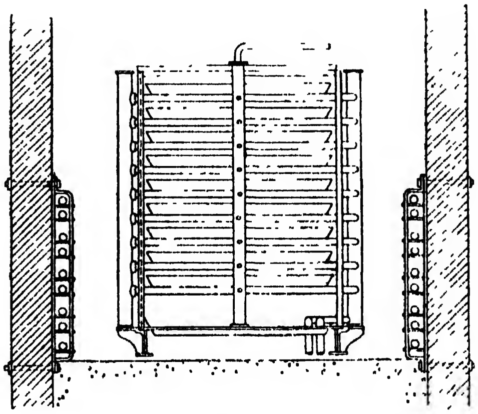

Fig. 6.

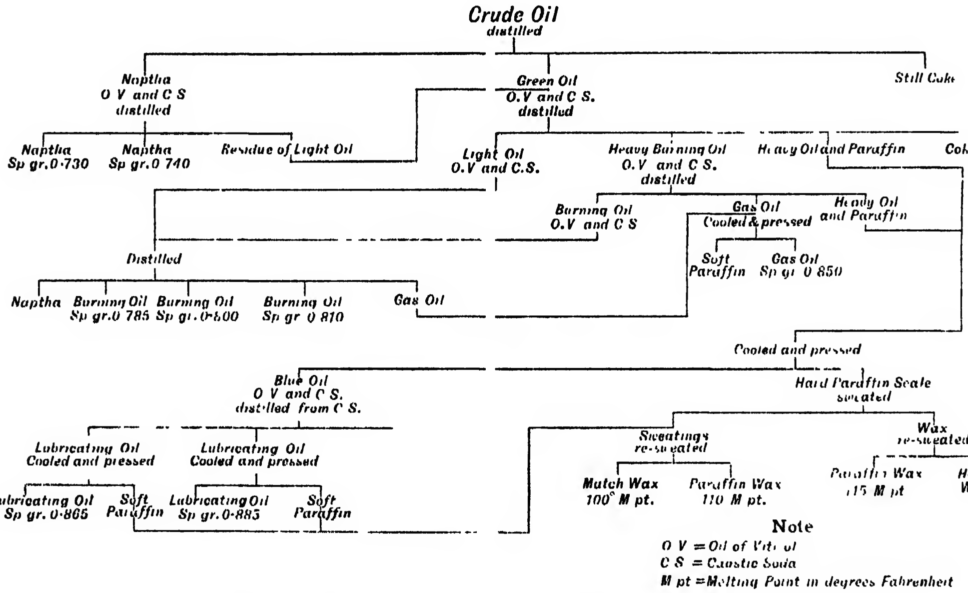
then refractionated to produce the different oils required. On treatment with sulphuric acid a tarry product is produced which is removed from the oil. This tar is then treated with water, when the tar and acid separate. The acid is used for making sulphate of ammonia, and the tar is burnt under the stills. Consequently, the distillation is carried out without cost for fuel, except what may be necessary for steam-raising.

After purification of the oil it is, as already mentioned, redistilled, and at one stage a heavy or "green oil," as it is called, is obtained. This is semi-solid and is placed in the paraffin sheds to be cooled. It is then filter-pressed, when the paraffin scale is obtained. The cakes are transferred from the filter press to hydraulic presses, where the remainder of the oil is squeezed out. The paraffin still contains small quantities of oil, which give it a yellow colour and lower its melting-point. To rid it of the last traces of oil it is sweated—that is, placed on large iron trays having false bottoms of iron lattice-work, water being pumped in to cover the lattice-work. Fig. 6 illustrates the Henderson sweating trays. The "scale" is melted and pumped into each tray to a depth of about 2 in. It is then allowed to cool and solidify. The water is run off, and the temperature of the chambers in which the trays are placed is gradually raised

by steam-heating. The scale on heating expands and becomes porous, and the oil in it slowly drains out. The sweating is continued until the desired melting-point is obtained. The paraffin so obtained is finally melted, mixed with powdered charcoal to decolourise it completely, passed through filter paper and then into moulding trays.

Shale oil is mainly a mixture of the paraffin and olefine series of hydrocarbons, but contains a small admixture of hydrocarbons of the naphthene and benzene series. The paraffins and olefines occur in the motor spirit and in the burning oils. In the heavier products, such as solid paraffin wax, the paraffin series alone is present. On the other hand, the lubricating oil is a mixture of olefines and paraffins. The crude oil also contains phenolic and nitrogen compounds, both of which are removed by the acid and alkali treatments. Unsaturated sulphur compounds which are present in the crude oil give it a very unpleasant smell, and the object of the refiner is to remove these, but not to remove the olefines. The olefines, as has already been mentioned, dissolve in strong sulphuric acid; therefore, if large quantities of acid were used in the refining process, the yield of oil would be reduced and the cost of refining increased. Only sufficient acid for purification purposes may, therefore, be added.

A general scheme showing the products obtained from oil shale is shown above. Shale does not itself contain oil. It is only produced by the destructive distillation of the organic matter contained in it. The oil-producing material in shale is called kerogen, and this, when subjected to low-temperature distillation, splits up into gases and the products we have been examining. The upper part of the retort, it will be remembered, is heated to a temperature of about 500° C., and it is here that the oil is produced and distilled off. As the shale drops down into the lower parts of the retort, it becomes more strongly heated to 700° or 800° C., and steam is passed in: here ammonia is produced. If the fresh shale were heated at the commencement to 700° or 800° C., a different class of oil would be produced and much larger quantities of gas. We should obtain more hydrocarbons of the aromatic series, and less lubricating oils and paraffin wax. In the shale-oil works the problem is to obtain as much oil and wax as possible, also sulphate of ammonia. It is, therefore, necessary to employ a low temperature at the commencement to obtain the oil, and a higher one at the end to get the greatest yield of ammonia. In gasworks' practice the opposite is the case. Gas is the main product. Consequently, the coal is heated to a high temperature, and large volumes of gas are obtained, together with hydrocarbons of the aromatic series. Owing to the large demand for oils, low-temperature processes of carbonisation have recently come very much to the front again. It is found that coals, when distilled at low temperature, yield paraffin and olefiant hydrocarbons, and only small quantities of oils of the aromatic series.



Low Temperature Carbonisation.

Recently a great deal of experimental work has been carried out in connection with the distillation of coal, lignite, shale and peat, and if the rather extravagant hopes of those who designed the various retorts have not matured, it has at any rate been proved that large yields of valuable oils can be obtained at a comparatively low cost for fuel and labour. There has been far too much loose talk about extraordinary yields of motor spirit, and those interested have endeavoured to squeeze out every drop of so-called spirit and have greatly exaggerated the actual yield of this very saleable article. Sufficient attention has not been directed to the important fuel oil which is obtained in much greater abundance. There are also large quantities of intermediate oils and considerable quantities of paraffin wax. The methods of distillation have not been sufficiently studied, and crude products have been classified as if they had been refined. Owing to the exaggerated claims of inventors, much disappointment has been met with by coal-owners and others who have subjected their minerals to distillation on the various retorts. Personally, I believe that there is a very great future in front of distillation at low temperatures, but we must get away from wild-cat schemes and exaggeration. One of the chief points to consider is: What does the market require? Is it a smokeless fuel, with good oil and a minimum quantity of sulphate of ammonia, or a very poor oil with a maximum yield of sulphate of ammonia and large quantities of gas? or, thirdly, a good yield of good oil, large quantities of gas and of sulphate of ammonia?

1. The first is a low-temperature carbonisation process.
2. The second is a producer-gas problem.
3. The third is a combination of low temperature carbonisation and afterwards producer gas.

In the original coalite process the first-mentioned was aimed at—that is to say, to produce a good smokeless fuel and ammonia, oil and gas being by-products. The same remark applies to the Del Monthe and the Tarless Fuel Syndicate processes. In other cases, particularly in dealing with peat and with coal residues, the second process was the one most favoured, for example, by the Power Gas Corporation, Ltd. In this process the material dealt with is burnt in a mixture of air and steam, the carbon is completely burnt, most of the nitrogen present in the original material is converted into ammonia, and a large volume of producer gas is obtained. The tar, however, which is also formed, yields a very poor oil. In industrial centres, where large quantities of cheap gas are valuable for motive purposes or for heating furnaces, the second will be by many considered the best business proportion. I am not certain, however, that a combined process will not in the long run be the most economical. There is not always a good market for smokeless fuel; for oils the market is always on the increase, and sulphate of ammonia is always, and will be always, a valuable fertiliser. If at the same time producer gas can be produced at a very low cost, another source of profit is present.

When coal or lignite is distilled at low temperature, oil is obtained together with gas and ammonia. The amount of oil produced depends mainly, but not entirely, on the amount of volatile matter present. Generally speaking, for each per cent. of volatile matter present one gallon of crude oil may be expected. This, however, is not reliable, because with some coals less than one gallon per cent. is obtained, and with other coals considerably more. The subject is one of great interest and would well repay further research—not on a laboratory scale, however. It is necessary to do it on a fairly large plant.

The first process may be carried out by itself or as a prelude to the third—that is to say, the coal, lignite, shale or peat is first distilled at a low temperature, which produces the oil and a certain quantity of ammonia and gas. The product remaining, which carries most of the fixed carbon and a certain proportion of volatile matter, is then treated in a producer, when the rest of the ammonia is obtained, together with a large amount of gas and a small quantity of tar. It is very doubtful whether such a process would be satisfactory in dealing with shales, which always have a large percentage of mineral matter. Shales certainly must be distilled at a low temperature, but should then be acted upon by steam at a higher temperature to obtain the maximum yield of ammonia. This need not necessarily be done with the vertical retorts used in Scotland, but could be carried out by modifying other forms of retort. Very good yields of oil have, for example, been obtained on retorts working on the Del Monthe and the Tarless Fuel Syndicate principles.

The Del Monthe is a continuous working retort which has an endless screw in the centre. The screw carries the coal or shale forward

through a cool and then a hotter zone until it is dropped into the hopper. The retort is of the horizontal type and is built at an angle of about 30°, the higher end being the hotter. The material is fed into the lower end and continuously discharged at the upper end. The gases and oil vapour produced by the carbonisation are caused to pass back through the cold material. This has a twofold effect. The gases and oil vapour are partially cooled, and thus decomposition is prevented, and as the gas parts with its heat the material fed in becomes heated. The actual form of the retort is a long iron tube which is heated externally. The endless screw is cast upon a tube, which is heated internally by a form of Bunsen burner, so that the material is heated both from the outside and inside. Small quantities of steam are allowed to pass in at the hotter end of the retort, or water is allowed to drop in, which answers the same purpose. If the material being dealt with contains large quantities of moisture, such, for example, as peat, then the admission of steam or water is unnecessary. The oil and gases as they leave the cooler end of the retort are passed through condensers and scrubbers, where the oil is collected in fractions and the ammonia washed out of the gas. The uncondensable gas is collected in a gasometer, and is employed for heating the retort. As a rule, more gas is obtained than is necessary to carbonise the product under treatment. The residual gas can be employed for raising steam for power purposes. About 5,000 cubic feet of gas is obtained per ton which differs from ordinary coal gas, as it is relatively poor in hydrogen, but rich in carbon monoxide and saturated hydrocarbons. When a non-coking coal is carbonised in this retort a useful smokeless fuel is obtained which contains from 8 per cent. to 11 per cent. of volatile matter. Most of the nitrogen remains in the fuel, and the question which arises is whether the product shall be sold as a smokeless fuel or shall be burnt in a producer to obtain ammonia and gas. There should be no difficulty in discharging the hot material directly into a producer, and thus economising heat. In dealing with shales, it would probably be better to lengthen the retort and to increase the heat at the far end, and at the same time to pass in superheated steam. Partially carbonised shale is useless as a smokeless fuel, owing to the large amount of mineral matter present, and would not, therefore, burn satisfactorily in a producer.

Bituminous and coking coals cannot be satisfactorily carbonised in the Del Monthe retort as at present constructed. They swell up, and in a short time absolutely block the working of the archimedean screw. By increasing the distance between the screw and the sides of the retort and altering the pitch of the screw this may to a certain extent be overcome; but it is doubtful whether a mechanical arrangement which depends upon the forward carry of a screw will ever be satisfactory with a coking coal. With lignite, shale, peat and wood the method works exceedingly well.

Appended are the results obtained from the carbonisation of a shale and coal on this retort:—

SCOTTISH CANNEL COAL.

Moisture	7·30 per cent.
Volatile matter	31·47 ,,
Fixed carbon	36·93 ,,
Ash	24·30 ,,

Yield of oil, 37 gallons per ton.

Approximate Yield of Oil after Fractionation.

Motor spirit	1·0 gall. per ton.
Fuel oil	6·3 ,, ,,
Heavy oil	16·9 ,, ,,
Wax	3·0 lb. ,,
Pitch	124 0 ,, ,,

NEWFOUNDLAND SHALE.

Moisture	1·54 per cent.
Volatile matter	22·35 ,,
Fixed carbon	2·92 ,,
Mineral matter	70·65 ,,
Nitrogen	0·24 ,,
Sulphur	2·30 ,,

On distillation 26 gallons of crude oil was obtained per ton of shale, the specific gravity of the oil being 0·920. On fractionation the following fractions were obtained:—

Water	0·05 per cent.		
Oil to 150° C.	1·20	,,	Sp. gr. 0·796
,, 250° C.	16·50	,,	,, 0·840
,, 360° C.	62·20	,,	,, 0·902
Residue	13·00	,,	
Loss	7·05	,,	

The process developed by the Tarless Fuel Syndicate works on quite different lines. The retort is vertical, and consists of two concentric cylinders between which the material to be carbonised is charged in. The heat is obtained in the first place by a producer, and afterwards by burning the gases obtained by the carbonisation. The flame passes round the retorts and up through the central cylinder, which is fixed to

the sides of the outer tube by radial flanges which serve to distribute the heat. The retort is charged with the material to be carbonised, which is first passed through a crusher to break it into pieces about 2 in. square. The retort is then closed, and a vacuum of about 27 in. put on to it. The gases as they are produced are thus drawn off through the condenser system, and the carbonisation takes place at a lower temperature than it would do under atmospheric pressure. Furthermore, another advantage of the vacuum is that the gases are immediately led away from the hot retorts, and thus decomposition is prevented. Every three or four hours the material is discharged by opening the tops and bottoms of the retorts and pushing down the charge by means of iron rods.

These retorts will deal with both non-caking and with caking coals, and a most excellent smokeless fuel is produced. Indeed, with coals which would ordinarily be considered non-caking a very good caked material is obtained. Gradual heating of the coal causes greater swelling, and this is increased by the vacuum, which abstracts the gases as they are produced from the more or less pasty material. The caking of the coal does not cause it to adhere to the sides of the retort, and there is no difficulty in pushing it down when the bottom is opened. The yield of oil is very similar to that obtained on the Del Monthe retort. The amounts of ammonia and gas produced are also very similar. Instead of producing a smokeless fuel the product can be burnt in a producer, and excellent results have been obtained in this way. Appended are the results of a coal and a shale which were treated on these retorts:—

YORKSHIRE COAL.

Analysis.

Water . . .	4·95 per cent.
Mineral matter	5·13 ,,
Volatile matter	29·49 ,,
Free carbon .	60·43 ,,
Nitrogen . .	1·40 ,,
Sulphur . .	3·22 ,,

On carbonisation, 18·0 gallons of water-free oil were obtained per ton of coal, which yielded:—

Motor spirit	3·00 gall. per ton.
Intermediate oil . . .	2·51 ,, ,,
Fuel oil	8·50 ,, ,,
Paraffin wax	8·00 lb. ,,
Pitch	50·00 ,, ,,

The yield of sulphate of ammonia was 22 lb. per ton.

SHALE FROM BULGARIA.

Analysis.

Moisture	0·46 per cent.
Mineral matter . . .	65·31 ,,
Volatile matter . . .	34·14 ,,
Fixed carbon	0·09 ,,
Nitrogen	0·17 ,,
Yield of crude oil . . .	27 gall. per ton.

On fractionation:—

Distilled below 160° C. .	2·20 gall. per ton.
,, ,, 270° C. .	8·75 ,, ,,
,, above 270° C. .	11·93 ,, ,,
Residue	27·66 lb.

The coalite retorts are long cylindrical iron tubes which have a slight taper from the top to the bottom. The products of distillation are led off at the top, and the gases are scrubbed and worked in the usual manner. The oils produced are similar to those just described—that is, they contain mainly paraffin and olefine hydrocarbons and very little benzene and aromatic hydrocarbons. The following is an analysis of coalite tar made by Mr. A. R. Warnes:—

Distilled to 170° . . .	10·8 per cent.
,, 170°–270° .	20·0 ,,
,, 270°–350°	30·0 ,,
Pitch	39·2 ,,

There are enormous beds of poor qualities of coal which can be readily distilled on a low-temperature plant, and will yield valuable fuel oils and sulphate of ammonia. Some of the higher fractions, after the removal of the paraffin wax, can be used as lubricating oils. There are also great peat bogs which at present are of practically no use. Peat, when partially dried and distilled at low temperatures, yields large quantities of oils which are rich in hydrocarbons of the paraffin series. The lower fractions can be used as motor spirit, the higher as a fuel oil. A peat-fuel oil which I have analysed, and which still contains the phenolic bodies which lower the calorific value, has a calorific value of 16,500 B.Th.U. The yield of oil from the particular peat from which this fuel oil was obtained was about 30 gallons per ton of peat carbonised.

Another source from which considerable quantities of oil is obtained is from the blast-furnace recovery plant. In Scotland, and in some part of the north of England, splint coal is employed in the blast furnaces in place of coke. Bearing in mind that blast furnaces are employed for smelting iron, anyone who has seen the white-hot liquid metal streaming out

of the tap-hole would hardly be inclined to consider that the distillation of coal in the furnace was a low-temperature one, and yet it is. The coal is fed in at the top of the furnace, which is the coldest zone, being mainly heated by the hot gases which pass up. The volatile matter is driven off as the coal and iron ore gradually pass down the furnace, and the actual reduction of the ore is produced by the coke formed as the volatile matter is driven off from the coal. The top of the furnace is, of course, closed in, and the gases, together with volatile matter, are immediately drawn off and passed through dust arrestors, and then through a complicated cooling and scrubbing system. Sulphate of ammonia is produced from the condensed and scrubbing water, and the heavy tar, having a specific gravity of 0·950 to 0·960, is distilled, giving a light and heavy oil. These oils contain about 20 per cent. to 25 per cent. of phenolic bodies, which make very good disinfectants. The pitch left after distillation, although not quite so good as that produced from the gasworks, obtains a ready sale. The oils make very good fuel oils, although at one time there was a difficulty in disposing of them. Enormous quantities of gas are obtained and used as motive power for gas-engines and for burning under boilers. The large residue is employed as a fuel for steel furnaces. The oils obtained consist largely of hydrocarbons of the olefiant series and of methylated aromatic hydrocarbons. There is very little paraffin wax present. The yield of tar oils from the blast furnaces in the United Kingdom exceeds 200,000 tons per annum.

In dealing with oils obtained from oil-wells or by the distillation of shale or from any other source, there are always certain products which are difficult to dispose of. There is a ready sale for oils distilling below 150° to 160° as motor spirit. Then there is an intermediate fraction from 150° to, say, 300°, which, if it contains chiefly paraffin hydrocarbons, is useful for illuminating purposes, but fetches a much lower price than the lower boiling oil. The employment of this oil, of which there are large quantities, depends upon the amount required for burning in lamps. Since the introduction of the incandescent gas-mantle and electric light, the requirements of oil for burning purposes are much less than formerly, and consequently there is a glut of oils boiling at this particular range of temperature. The next fraction forms the fuel oil; but it must be pointed out that the boiling-point of a fuel oil does not much matter, provided the flash-point is not too low and the viscosity when cooled to 32° F. not too great.

The following are the British Admiralty specifications for oil fuel:—

"The flash-point should not be lower than 175° F. close test (Abel or Pensky-Martens). [In the case of oils of exceptionally low viscosity, such as distillate from shale, the flash-point must not be less than 200° F.]

"The proportion of sulphur contained in the oil shall not exceed 3 per cent.

"The oil fuel supplied shall be as free as possible from acid, and in any case the quantity of acid must not exceed 0·05 per cent., calculated as oleic acid, when tested by shaking up the oil with distilled water, and determining by titration with decinormal alkali the amount of acid extracted by the water, methyl orange being used as indicator.

"The quantity of water delivered with the oil shall not exceed 0·5 per cent.

"The viscosity of the oil supplied shall not exceed 2,000 seconds for an outflow of 50 cubic centimetres at a temperature of 32° F., as determined by Sir Boverton Redwood's Standard Viscometer (Admiralty type for testing oil fuel).

"The oil supplied shall be free from earthy, carbonaceous, or fibrous matter, or other impurities which are likely to choke the burners.

"The oil shall, if required by the Inspecting Officer, be strained by being pumped on discharge from the tanks, or tank steamers, through filters of wire gauze having 16 meshes to the inch.

"The quality and kind of oil supplied shall be fully described. The original source from which the oil has been obtained shall be stated in detail, as well as the treatment to which it has been subjected and the place at which it has been treated.

"The ratio which the oil supplied bears to the original crude oil should also be stated as a percentage."

The minimum flash-points adopted for oil fuel by other navies are:—

Germany	187° F.
France	200° F.
United States	150° F.
Russia	212° F.
Italy	212° F.
Austria	248° F.

The requirements for fuel oils are rapidly increasing, and this is one of the reasons why I have such faith in low-temperature carbonisation,

because a large proportion of the oil produced can be employed as a fuel oil.

Our own Admiralty are employing oil fuel to a greater and greater extent; the policy of the United States is to use oil exclusively as fuel for the battleships, cruisers and torpedo boats. They have now built, or are building, the following vessels which will employ only oil fuel: Four battleships, forty-one destroyers, one monitor, fifty submarines, three tank vessels, three tenders, seven oil barges, and several small vessels and tugs.

Lubricating oils are usually obtained in the higher fractions. Some oils, however, even when they have a high specific gravity, lack the viscosity necessary for use as lubricants, and the problem then arises what to do with them.

Probably these oils might be profitably cracked, and thus be converted into oils of lower gravity and boiling-point.

GROWTH OF THE THREE GREAT FLEMISH PORTS.

The Milanese journal *Il Sole* has recently published an interesting article on the remarkable growth of the three ports of Amsterdam, Rotterdam, and Antwerp. Written by Signor Gino Borgatto, a member of the Naples Chamber of Commerce, who visited these ports only a few weeks previous to the outbreak of the war, this article cannot fail to be read with special interest at the present time.

From their geographical position, Antwerp and Rotterdam are eminently favourably situated for the transhipment trade: the first on the banks of the Scheldt, about sixty miles from the North Sea, and the second on the River Maas, only fifteen miles from its mouth at the Hook of Holland. These ports are in direct communication, by means of the great waterway of the Rhine and the immense network of navigable canals, with the heart of Germany, as well as with the principal industrial and commercial centres of Belgium and Holland.

With such a vast hinterland, and with its splendid natural and artificial advantages, it is not surprising that Antwerp and Rotterdam should have been able, of late years, to secure so large a share of international trade, and so become formidable rivals to the premier port of Germany, namely, Hamburg. One fact common to all three ports is that their increased prosperity is of comparatively recent growth, as it may be said to date from the middle of the nineteenth century.

In 1850 the total number of vessels that entered the Port of Rotterdam was only 1,940, with a tonnage of 346,180 net, of a total of 6,961 vessels and 767,710 tons that entered all the ports of Holland that year.

The gradual increase in the movement of shipping at this port, as compared with that of all the Dutch ports, is shown by the following statement:—

Year.	Port of Rotterdam.		Totals for all Ports of Holland.	
	Number of Vessels.	Net Tonnage.	Number of Vessels.	Net Tonnage.
1860	2,449	592,978	8,714	1,458,894
1870	2,973	1,026,348	8,351	2,037,491
1880	3,456	1,681,650	(No figures given)	
1890	4,535	2,918,400	9,475	5,446,100
1900	7,268	6,326,900	12,037	9,450,700
1905	8,138	8,339,300	13,709	11,738,200
1910	9,338	10,658,800	14,874	13,034,400
1912	10,208	12,094,000	17,000	17,335,900

It will be seen that the tonnage of the vessels which entered this port during the last quarter of a century has increased 414 per cent.

Less striking has been the growth of the port of Amsterdam, the tonnage of which that entered has increased 273·4 per cent. during the last twenty years:—

Year.	Number of Vessels.	Tonnage (Displacement).
1880 . .	1,611	2,980,400
1890	1,575	4,200,000
1900	2,111	7,060,055
1910	2,288	10,074,560
1913	2,597	12,303,055

The shipping returns of the Belgian port of Antwerp plainly show the wonderful growth of the trade of this city since the middle of the last century:—

Year.	Number of Vessels Entered.	Tonnage.
1850	1,406	239,165
1870	3,967	1,362,606
1880	4,475	3,063,825
1890	4,728	4,506,177
1900	5,414	6,720,150
1905	6,094	9,900,305
1910	6,770	12,654,153
1911	6,896	13,849,633
1912	6,973	13,797,000

From this it will be seen that whilst the number of vessels frequenting the port has only increased about 27 per cent., the tonnage entered has more than doubled during the last twelve years.

Compared with some of the other principal ports of Europe, Antwerp and Rotterdam hold important places as regards the tonnage of the vessels that entered in 1912:—

Port.	Number of Vessels.	Total Net Tonnage.
London	23,572	18,745,900
Liverpool . . .	20,868	15,147,100
Antwerp . .	6,973	13,797,000
Rotterdam . . .	10,208	12,094,000
Marseilles . . .	8,246	9,682,300
Naples . . .	10,076	9,377,200
Genoa	6,014	7,105,500
Bremen	5,739	4,210,400

The growing importance of Antwerp as an international port of transit may be estimated from the following figures, which give the value of the goods landed from 1850 to 1911 inclusive:—

Year.	Total Value of Goods Landed.		Value of Goods in Transit.	
	Francs.	£ Sterling.	Francs.	£ Sterling
1850 .	431,900	17,276	201,200	8,048
1870 .	1,600,900	64,036	831,600	33,264
1880 .	2,897,600	115,904	1,008,400	40,336
1890 .	3,109,400	124,376	1,511,100	60,444
1900 .	4,138,600	165,544	1,674,600	66,984
1905 .	5,401,800	216,072	1,922,900	76,916
1910 .	7,672,300	306,892	2,287,200	91,488
1911 .	8,088,800	323,552	2,298,900	91,956

It is estimated that in 1912 no fewer than 136,887 craft of various descriptions, with a carrying capacity of 29 millions of tons, were employed on the inland waterways in connection with these ports.

The following statistics will give some idea of the importance of the three ports as regards facilities for handling merchandise.

Rotterdam has eight floating docks, with a total capacity of 50,672 tons. The total area of the various docks is 269·9 hectares (666½ English acres). Length of quays, 39·8 kilometres (130,544 lineal feet).

The length of the quays at Amsterdam has been nearly doubled during the last twenty years from 4,850 metres (15,908 feet run) in 1892 to 6,220 metres (20,401 feet) in 1902, and 7,040 metres (23,091 feet) in 1912.

At Antwerp, in 1912, the length of the eleven principal quays was 14,941 lineal feet, and that of the sixteen docks 64,118 feet, making a total of 79,059 feet run of quay accommodation at this port.

A KHAKI DYE.

At the present moment, when the demand for khaki is practically unlimited, attention may be directed to a communication by Mr. M. Fort, M.Sc., of the Technical College, Bradford, on "A Method of Developing a Fast Chrome Brown on Wool," which appears in the July number of the *Journal of the Society of Dyers and Colourists*.

Mr. Fort was led to experiment with gallic acid, a simple derivative of natural products, the supply of which is practically unlimited, and the production of which does not compromise the manufacture of explosives in any way. It has been and is being largely used on that account doubtless by dye manufacturers themselves, as it readily gives rufigallol and galloflavin, without the benzoic acid required to make anthragallol.

The scientific basis of the new method lies in the diazotisation of wool, its coupling with gallic acid, and fixation of the dyestuff thus formed by means of chrome. It is a perfectly general method admitting of the use of many phenolic bodies other than gallic acid if and when such are available. Tannic acid itself may be substituted for gallic acid in the process, giving somewhat similar shades but inferior in depth, with the added risk also of depreciating the handle of the wool by making it harsh, such risk being entirely absent when gallic acid is employed.

It is unnecessary to detail the various trials which were made to discover the best method of producing a shade on the basis adopted above. The best method is found to be as follows: Wool is chromed in the ordinary way to produce a green chrome mordant, *e.g.*, 3 per cent. bichrome, 2½ per cent. tartar, or with any other suitable assistant, bisulphite after-treatment, etc., which may be in ordinary use at present for this purpose. The dyebath is made up for dyeing a shade of medium depth with 2 to 3 per cent. gallic acid, 4 per cent. sodium nitrite, and 5 per cent. acetic acid, reckoning on a standard bath thirty times the weight of the wool. The chromed wool is entered cold or lukewarm, the temperature raised to the boil slowly and the bath boiled one hour. The shade develops slowly and evenly with rise in temperature, level dyeing and good penetration being easily assured in the case of either light or

deep shades. At least an hour's boiling is necessary to obtain full fastness by complete fixation of the chrome lake. The bath is not exhausted. The fastness of the shade obtained is good to light, very good to heavy milling, alkalis, and acids. The wool is not deteriorated in tensile strength, handle, milling properties, etc. The shade may be varied by addition of suitable dyes, *e.g*, mordant dyes which are unaffected by nitrous acid.

By the method described above the brightest shades are obtained in wooden vessels, iron causing a dulling of the shade, while copper also exerts some influence on the shade, but to a much less extent. The effect of copper vessels such as are in common use for top dyeing may be overcome by use of copper in mordanting; *e.g.*, 1 or 2 per cent. copper sulphate crystals along with the bichrome. The shade thus obtained is a full brown of yellowish cast, and is faster to light. In a three months' exposure test at similar depths of shade it proved superior to Khaki Brown W. The fastness to light is unimpaired by heavy milling before exposure. This brown, really an ingrain brown on a copper-chrome mordant, is one of the fastest browns known on wool, being very good indeed to all usual agencies. It will be noted that all additions to the dyebath are perfectly soluble, and this allows of use on various kinds of material dyed in special machines.

MACHINERY TRADE IN JAPAN.

Some Interesting Facts and Figures.

The following information on the machinery trade of Japan has been received from H.M. Commercial Attaché at Yokohama.

In the 1913 report on the trade of Japan it was explained that, inasmuch as it takes a long time to obtain delivery in Japan of goods from abroad, the heavy importations of machinery in 1913 were the outcome of the optimistic feeling which prevailed in 1911, and it was shown that, owing to the depression in the business world in 1912, it might safely be anticipated that the machinery figures would show a large falling-off in 1914. This prophecy proved quite correct, for whereas the total for 1913 was £3,752,700, it dropped to £2,500,000 in 1914.

The United Kingdom remains well at the head of the list, and now enjoys more than 50 per cent. of the business, which is better than for a long time past. Although, as explained above, the war was not responsible for the falling-off in the orders placed for machinery to arrive in 1914, it certainly interfered to a considerable extent with the deliveries of German machinery. This can best be gauged by comparing the figures up to the end of July with those for the whole year. Up to the time when war broke out Germany had 25½ per cent. of this business; by December the percentage had dropped to 22. There is still a little more to come forward from Tsingtao and from places where German ships have run for shelter; but when this has all arrived, imports from Germany will cease completely, and British makers will at last have a fair chance of competing, and it is to be hoped they will take full advantage of it.

Since war broke out very few orders have been placed. At first there was an idea that it would be impossible to get delivery; then, when it was seen that this would not be the case, buyers still held off owing to the general uncertainty as to what the future held in store; but confidence is gradually returning, and it is thought that within the next few months it will be possible to obtain a certain amount of orders. There are some points, however, which should be borne in mind. The most important is that Government Departments, in pursuance of the policy of "Support home industries," place their orders in Japan whenever they can possibly do so. Another important factor is that Japanese engineering works are increasing in number and in capacity. Were it not for the heavy import duties it would, of course, be impossible for them to compete in a great many lines; but the duty and the freight rates together give them a big advantage, which enables them to come fairly near British prices.

H.M. Commercial Attaché suggests that makers of small machinery of a class which is sold in quantities in standard sizes, such as gas-engines, electric motors, pneumatic drills, pumps, etc., should send out their goods for sale consigned to firms of high standing. By this means stocks can be kept, and a purchaser who finds that he can buy from stock will be more likely to go to the importer than if he has to wait for eight or nine months for delivery—in the latter case he will be tempted to try a Japanese-made copy of a foreign machine, which he can get quicker and cheaper. The importing firms themselves are rarely willing to tie up their capital in stocks, as the profit they can obtain is often eaten up by local high interest charges, while the manufacturer, who has naturally added a considerable amount to his price for standing charges and profit, would only be paying interest on the actual first net cost, and he would also probably be able to borrow money at a cheaper rate in the United Kingdom. The merchant would keep the bulk of the goods in bond, so that if it should prove necessary to ship them to some other market, this could be done without loss of the duty.

The reason for bringing this suggestion forward is that the manufacture of machinery in Japan is making considerable progress, and unless some thought is given to the problem, United Kingdom manufacturers may loose a part of the business which they now enjoy. It should also be stated that the idea mentioned above has been tried during the past two or three years with, as far as can be learned from the parties concerned, a considerable amount of success.

One of the interesting features of engineering work in Japan is the very large number of tiny

establishments in existence—places which appear in engineering directories as "So and So's Engineering or Iron Works," but which really consist of a workshop with one lathe and two or three employees. They have no establishment charges, they work for a very small profit, and consequently they are able, in tendering for Government work, to put in exceedingly low prices. They do not quote direct- they are too small to do that—but a sort of broker takes the contract from the Arsenal or other Department, and then sublets it to those different works. As they are on such a small scale, there is a good deal of irregularity in the output, and the percentage of rejections is large; but none the less competition from such work is very severe.

Naturally, the above remarks do not apply to the big works, which are run on more or less foreign lines, although, even in these, there are points of difference which immediately strike the foreign engineer. For instance, the foreman is invariably on the side of the men and against the office. Then, again, there are no apprentices, and no men of a better class gaining practical experience by putting in a certain number of years in the works. The engineers are nearly all graduates of technical colleges with little practical experience. The workmen, on the whole, are industrious and eager to learn; but their rice diet appears to be against them, for in engineering jobs they lack the necessary bodily weight, and the percentage of days when they are absent on account of sickness is very high. Nevertheless, as their wages are low and as they are gradually learning and acquiring experience all the time, it is well worth while for any British maker of machinery who supplies either the Japanese or the Chinese market to watch developments, and to change his policy as and when required.

ENGINEERING NOTES.

Recent Developments in Electric Traction.—In the endeavour to find the most economical method of applying electrical energy to the working of railways many systems have been installed. It would be most desirable, on account of junctions and places where companies have running powers over each other's lines, that a uniform system should be adopted in the future; but although the successful results have warranted the conversion from steam working, it has been very difficult to make a final decision as to which of the electrical systems is the most economical, as no two railways which have been electrified present the same conditions as regards distances, density of traffic, etc. The oldest and the most tried is the direct current system used in the Underground and in all tramways in London. More recently high tension direct current has made headway in America, and in Australia, where the Victorian Railway Commissioners have adopted this system. Italy favours the three-phase alternating current system, which, although requiring at least two conducting rails or overhead wires, presents great simplicity in other respects. Lastly, the single-phase alternating current used on the Brighton and South Coast line and many Swiss lines possesses great advantages, in that the current can be transmitted to the train at a high voltage, requiring only a single small overhead wire. The motor equipment, however, is costly and requires a special low frequency, *i.e.*, 15 to 25 cycles per second. The use of a mercury vapour rectifier on the locomotive to convert the single-phase alternating current to uni-directional current is under trial, and would enable direct-current motors and a standard alternating current frequency to be used. In the electrification of the Bluefield to Vivian section of the Norfolk and Western Railway in the United States, an alternative method has been put into operation in which a single-phase supply is converted to three-phase by means of a special rotating converter on the locomotive. It has thus become possible to utilise the special advantages of the three-phase induction motor for heavy traction, whilst retaining the simplicity of the single-phase distribution and collection. This system, which is unique in its application to electric traction, also lends itself to the return of energy to the line when a heavy train is descending a grade.

A Petrol Railway Coach in New Zealand and in the United States.—But there are other ways apart from steam of gaining power for traction, amongst others petrol, and one of these, termed the "Thomas" system, is thus detailed in a *Times* article referring to New Zealand. This plan, which depends on the use of two electrical machines (each about one-third of the normal horse-power of the prime mover), and a planetary gearing interconnecting them with the engine and the load, gives remarkable flexibility of control. Twelve forward speeds are provided; at top speed all the power is transmitted direct mechanically, but for starting or for climbing heavy gradients part is transmitted mechanically and part electrically. The vehicle runs equally well forwards and backwards; the change for continuous working is effected by reversing the direction of rotation of the engine, but when a change of direction is required for short distances, as in shunting, the transmission is effected electrically, one of the electrical machines coupled to the engine acting as a dynamo and driving the second machine, which is coupled permanently to one of the driving axles and acts as a motor. The engine is started electrically by passing the current from a battery through the first electrical machine. Power is supplied by a 200 horse-power engine of the V type made by Messrs. J. Tylor and Sons, London. This has eight cylinders, 7 in. in bore by 8 in. in stroke, and runs normally at 900 revolutions per minute, the maximum being 1,500 revolutions per minute. It is expected that the fuel consumption will be of the order of 200 ton-miles per gallon of petrol.

The vehicle, which is designed chiefly for suburban work, has a maximum speed of just over 40 miles an hour on the level, and is required to carry passengers and haul a 25-ton trailer up a gradient of 1 in 40 at 15 miles an hour, the gross load being then about 60 tons. The coach alone is to mount the gradient at 28 miles an hour, and it is estimated that it will haul a gross load of 85 tons up it at about 10 miles an hour. In ordinary service it will haul 25-ton trailers with a full complement of passengers, about 150 in all. The body is at present not fitted, as it is to be made at the Government railway works in Wellington.

What is said to be the largest petrol motor-car for railway use in the United States has been built by the McKeen Motor Car Co., Omaha, Neb. It is a baggage, mail, express, and power-car, equipped with a 300 horse-power engine which will furnish sufficient power to haul a standard car as a trailer. The engine is reversed by air-pressure mechanism, the control of which, together with the throttle, is placed on the right-hand side of the engine. The length of the car is 70 ft., and the total wheelbase is 44 ft. 2 in. The weight on the drivers is 33,800 lb. and the tractive effort exerted by the engine 8,200 lb. The car is intended for service on one of the branches of the Union Pacific Railway, and will be substituted for a three-car steam passenger train having a seating capacity of 70, whereas it will seat 78 passengers. A round trip of 206 miles a day will be made.

Magnet for Removing Metal from the Flesh.—A strong magnet for lifting weights is not an unusual engineering operation, but it is not customary to enlist a surgical one for the purpose. This is being done by one of the most powerful magnets in the world, and has been installed by the Westinghouse and Electric Manufacturing Company in the relief department of its East Pittsburg works. The magnet is mounted on a box containing the resistor, which is used to regulate the amount of current flowing through the coils. It requires 4,000 watts for its operation, or enough power to supply one hundred lamps of 32 candle-power each, and is designed for operation on 70 volts. It is not an infrequent occurrence for steel and iron workers to get bits of metal in their eyes or hands. Previous to the installation of a magnet the only means of removal was by probing, a method which is as uncertain as it is painful. Since this machine was put in operation, it is a very simple proceeding to extract such particles. The portion of the body in which the foreign particle is embedded is placed near the pole tip of the magnet, the switch is closed, and the magnet does the rest. Some remarkably small pieces have been extracted in this way. The pole piece is removable, a number of different shapes being supplied for various classes of work.

Rail Corrugation.—This is a matter concerning electric traction, in view of which an interesting experiment is being tried on the Huddersfield Corporation tramway system. Mr. R. H. Wilkinson, the general manager and engineer, has devised, the *Engineer* tells us, a differential gearing which has been fitted to eleven of the Huddersfield cars, his view being that by thus endeavouring to eliminate the slip and skid of the wheels the cause of the formation of corrugations will be removed. These eleven cars are running on a section from which the corrugations have been carefully ground out. So far sufficient time has not elapsed for any definite results to be obtained, but it is stated that the indications up to date are of a favourable nature. It had been anticipated that the use of differential gears would have led to some small reduction in the consumption of current, but this economy has not materialised, although, on the other hand, there is evidence of a distinct increase in the life of tyres.

A Flat Long-span Concrete Arch.—An arch of this description was built during the past year over the Aare River at Olton, Switzerland. Its span is 269 ft., and its rise 30 ft. 5 in., giving a ratio of span to rise of 8·8. The bridge is relatively narrow, being only 26 ft. wide between railings. The 16-ft. roadway is designed for 77 lb. per square foot and a waggon of 13 tons weight, while the footways are figured for 110 lb. per square foot. The arch is three-hinged. Its curve was laid out to follow the pressure line. The width of the barrel is 19 ft. 8 in.; the ring thickness is 62 in. maximum (at quarter points), 48 in. minimum (at crown), and 52 in. at skewbacks. The maximum stress in the concrete is somewhat below 700 lb. per square inch. The roadway, a 6-in. slab, is carried by four stringers supported directly on columns resting on the arch. The slab cantilevers out beyond the outer line of stringers to form the footways. Expansion joints in the roadway are provided over the springing line and at the point where the roadway merges into the arch barrel. Load tests under a 16-ton steam roller gave deflections of ⅛ in.

A Small Hydro-Electric Plant.—A small station designed to give satisfactory service to a town consisting of 400 people and at the same time return a reasonable earning on the investment, was recently completed at Waucoma, Iowa. It consists of a concrete dam of the ordinary reverse surge type, 193 ft. long and 12 ft. in height, giving a working head of 9 ft., and a power-house built of vitrified hollow blocks, with a reinforced-concrete floor and a roofing of asbestos shingle. The source of supply is a small, spring-fed stream, which runs through the centre of the town, with an average flow of about 16 cubic ft. per second. For developing the power there is a 20-in. Leffel wheel, directly connected to a 37 kilowatt three-phase, 60 cycle alternating current generator. There is also a 30-in. Leffel wheel belted to a generator shaft and connected with a friction clutch to be used in flood times. The plant was designed with a strict view to maintaining balanced

proportions and to meet with local conditions. Great care was exercised to purchase the correct machinery for the particular purpose. The plant is nearly automatic in operation, and gave a net earning of 10 per cent. during the first month it was operated. Since then the load has been increasing to such an extent that an earning of 15 per cent. is expected for the first full year of operation.

CORRESPONDENCE.

THE VALUE OF BIRDS TO MAN.

In the issue of your *Journal* for June 18th is a reprint of Mr. James Buckland's interesting article on "The Value of Birds to Man," taken from the report of the Smithsonian Institution. In it the following paragraph appears:—

"Those grass ticks which now make the keeping of most breeds of cattle impossible in Jamaica are not mentioned in the records of the early nineteenth century. The appalling destruction in more recent years of insect-eating birds, chiefly to supply the demands of the millinery market, has led to an inordinate increase of the ticks and to the dying out of all but Indian cattle. This correlation of birds and ticks—to say nothing of mosquitoes and other insect plagues in Jamaica —was put fully and circumstantially before the Secretary of State for the Colonies by a deputation in 1909."

Without wishing to imply that the ticks are not a serious handicap to the stock-raiser (or pen-keeper), I think it right to point out that the paragraph contains several statements which are exaggerated. First, it is not true to say that the keeping of most breeds of cattle in Jamaica is impossible. Secondly, it is not true to say that there has been an appalling destruction in more recent years of insect-eating birds, chiefly to supply the demands of the millinery market. Thirdly, it is not true to say that there has been an inordinate increase of ticks in more recent years. Fourthly, it is not true to say that all but Indian cattle are dying out.

The plague of ticks is to be dated to the purchase in the last twenty years of the last century of cattle from Central America, which introduced the blood parasite of tick fever.

The mongoose was introduced from India into Jamaica in 1872, in order to reduce the rats on the sugar estates. This they did, but by 1890 they had become such a nuisance, by reason of their killing of domestic poultry and wild birds, that a Commission of four sat on the subject. Two Commissioners found:—

"That the mongoose destroys young birds, kids, lambs, newly-dropped calves, puppies, kittens, also the young of the coney, poultry of all kinds, game such as partridges, quail, guinea-fowl, snipe, lapwing, ground doves, young John Crows, and all birds which nest on or near the ground, and their eggs; as well as snakes, ground lizards, frogs, turtle and turtle eggs, land crabs, and other useful creatures. We had evidence to show that the mongoose eats ripe bananas, pines, young corn, avocado pears, sweet potatoes, cocoas, yams, pease, and certain fruits, and that he is suspected of sucking the sugar-cane, also that he will eat meat and salt provisions, and can catch fish; in short, that he is, or has become, omnivorous."

The other two Commissioners stated that what was lost in poultry was gained in coffee, corn, and other crops.

As a matter of fact, the mongoose, which has certainly aided the increase of ticks by the destruction of tick-eating birds, does not now appear to be continuing to increase. Indeed, many sanguine people say they are diminishing. There certainly is not, and never has been, any appreciable destruction of insect-eating birds to supply the demands of the millinery market. A few humming-birds may be killed for that purpose, but there is no evidence that skins are exported as a commercial undertaking, and humming-birds' plumage is seldom, if ever, seen in the island as part of female attire. A number of birds are killed yearly by boys with stones, catapults, and various springes, but this is hardly peculiar to Jamaica. A Birds and Fishes Protection Law provides for the protection *throughout the year* of a large number of insect-eating birds; but it is true that this law is not so rigidly enforced as is desirable.

There are by estimate 116,000 horned stock in the island. Perhaps as many as 40 per cent. have not a drop of Indian blood in them, being chiefly of native breed, with admixture in many cases of Shorthorns, Herefords, Devons, Redpolls, and Aberdeen Angus, or dairy breeds. It is true that Indian cattle are much less attacked by ticks than European breeds and the infusion of Indian blood has considerably strengthened and made more resistant to ticks the other breeds; but to say that the latter have died out, or are dying out, is far from the truth.

The question of tick-destruction has, since the visit of Professor Newstead in 1910, received much more attention than it did some years ago, with beneficial results.

Finally, I may quote the opening sentence of a recently published article on "The Improvement of Native Cattle in Jamaica," by the Director of Agriculture: "The island of Jamaica is remarkably suitable for the breeding of cattle, and there are large areas of land where magnificent tropical cattle can be reared under economical conditions."

Kingston, Jamaica, July 29th, 1915. — FRANK CUNDALL.

GENERAL NOTES.

BOOKS FOR BRITISH CIVILIAN PRISONERS OF WAR INTERNED IN GERMANY.—The Board of Education has issued a request for books of an educational character for the use of the British civilian prisoners in the Concentration Camp

at Ruhleben in Germany. The books are needed for use in the educational classes in connection with the Camp Education Department, which has recently been formed for the benefit of the prisoners. The books required deal with English History and Literature, various branches of Science, Navigation, First Aid, Commercial Law, etc. Dictionaries, works of reference, and scientific periodicals would also be most valuable. Any communication on the subject should be addressed to Mr. Albert T. Davies, Board of Education, Whitehall, London, S.W., and he will supply a form on which intending donors can enter the books they are able and willing to give for the purpose. Donations of money are not directly asked for, but will be accepted, and utilised to the necessary extent.

TOURS IN FRANCE.—The Touring Club of France has issued a pamphlet intended to encourage visitors to France at the present time. The pamphlet gives a sketch of various tours which may be made in France, and, judging from its contents, there is no reason why those who are uncertain where to spend their holiday should not arrange to spend it in France.

COTTON INDUSTRY IN MANCHURIA.—In 1911 a company was organised at Mukden with a capital of £300,000 for the manufacture of cotton sheetings. The machinery comprises thirty looms, and the motive power is furnished by kerosene engines. About fifty operatives are employed, and the daily output is 1,200 yards. The same company works a cotton-mill at Liaoyang, which contains a total of twenty-four looms—sixteen for sheetings and eight for nankeens. The production of this mill in 1914 was 6,500 pieces of sheetings and 4,500 pieces of nankeens. A cotton-mill at Newchwang operates twenty power-looms for nankeens and thirty-six hand-looms for sheetings. Last year this mill turned out 11,000 pieces of nankeens and 10,000 pieces of sheetings. The output from these three small establishments is, at present, too insignificant to have any effect on the market; but, says the United States Consul-General at Mukden, it is worth noting as an indication that in time cotton manufacturing in Manchuria may become an industry of importance.

COTTON WASTE IN INDIA.—The war has opened up possibilities of creating several new industries in India. Hitherto, India has exported large quantities of cotton waste to Germany, and it used to fetch as much as Rs. 60 per candy. Since the outbreak of the war the export has ceased, and some of the captains of the mill industry are thinking how best to utilise the cotton waste, the price of which has dropped from Rs. 60 to Rs. 10 per candy. The waste was used in Germany to turn into coarse counts, which were used for manufacturing blankets, carpets, and other such articles. Some of the mill agents are contemplating the importation of waste cotton plants, so as to utilise the waste for the purpose of manufacturing blankets, carpets, etc., in India. It is to be hoped, says the *Times of India*, that this enthusiasm will not die out until somebody has turned to practical account the opportunity of supplanting German goods by those of Swadeshi make.

STERILISATION OF WATER FOR TROOPS.—A method for the sterilisation of water for troops in the field, and also for domestic and industrial purposes generally, has, it is stated by a French journal, been lately perfected by M. Billon Daguerre. This new method consists in the employment of the ultra-violet rays from an electric lamp submerged in the liquid to be purified. It appears from some experiments recently made with Seine water, artificially contaminated, that all disease-spreading germs were completely eliminated by this new process. The apparatus, which can be mounted on an auto-car, is capable of sterilising 10,000 litres (2,200 imperial gallons) per hour, with a current of 4 ampères at a pressure of 85 volts.

PAPER UNIFORMS.—Both Japanese and Russian soldiers are wearing paper clothes. "Kamiko," as paper clothing is called in Japan, is made of the real Japanese paper manufactured from mulberry bark. The paper has little "size" in it, and, though soft and warm, a thin layer of silk wadding is placed between two sheets of the paper, and the whole is quilted. Japanese soldiers realised the value of this kind of clothing when they had to weather a Siberian winter, but its only drawback is that it is not washable. A company in Yokohama is supplying large quantities of paper shirts to the Russian Army. They state, says the American Consul-General at Yokohama, that paper clothes are extensively manufactured in Japan. The garment sold by the firm is made of tough, soft fabric, strong enough to hold buttons sewn on in the ordinary way, and appears to be very serviceable.

NATURAL GAS IN CANADA.—Throughout the entire length of the intercolonial railway of Canada, running from the Atlantic seaboard to Montreal, the passenger cars are lighted with gas from the New Brunswick natural gas-fields, the product having been successfully used in place of the Pintsch gas, with which the lights were formerly charged. Gas is also used exclusively as fuel and for power generation in the car shops at Moncton, over 30,000,000 cubic feet having been consumed in one month, September last. The steady and reliable heat, according to the report of the Canadian Department of Mines, makes it an ideal fuel for forges, furnaces, and gas-engines; no time is wasted in firing up, and there is a considerable saving in expenditure. The gas from the Canadian Pacific Railway well at Medicine Hat is bottled in steel flasks, eight inches in diameter and fifty feet in length, and is shipped for use in lighting the cars. The pressure of the bottled gas is 1,700 lb.

Journal of the Royal Society of Arts.

No. 3,275. VOL. LXIII.

FRIDAY, AUGUST 27, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

THE "JOURNAL."

The Fellows will notice that the *Journal* this week appears with a white cover, instead of the usual grey one. This alteration is purely a measure of economy, and is intended to be temporary, for the duration of the war only. As soon as possible the old *Journal* cover will be resumed. The change enables a certain saving to be effected in the cost of printing. In other respects the *Journal* will be precisely the same as heretofore.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

OILS, THEIR PRODUCTION AND MANUFACTURE.

By F. MOLLWO PERKIN, Ph.D., F.I.C., F.C.S., M.Inst.P.T.

Lecture III.—Delivered February 1st, 1915.

It has already been mentioned that when oils, particularly those of high boiling-point, are heated, decomposition takes place and lighter fractions are produced. This peculiarity was first noticed in America, and has since then been made use of for obtaining larger yields of illuminating oils. Oils which boil below 200° C. can be distilled with very little decomposition; those of the paraffin series probably without any. Even with many lighter oils, however, slight decompositions do take place. For example, if an oil distilling up to, say, 170° C. is repeatedly fractionated, residues will be obtained which will require a higher temperature than 170° C. before they will distil over, showing that the heat has produced a change, and on redistillation of the bulk the same phenomenon will be noticed. The action of heat on oils is really either one of decomposition where larger molecules break down into lighter molecules, or in which a shifting of the hydrogen atom takes place, which generally resolves itself into polymerisation and the formation of still higher molecules. The character of the product obtained when an oil is heated depends upon the nature of the oil, the temperature to which it is heated, and the pressure. Generally speaking, when an oil is heated, decomposition and polymerisation take place at the same time. That is to say, if an oil is being cracked in order to obtain a lighter oil of lower specific gravity—for example, to produce a motor spirit—the residue will have a higher specific gravity and boiling-point than the original oil. By gradually heating the residue further quantities of light oil may be obtained, but at the same time a heavier and heavier residual product will result, until finally asphalt is produced, which on further heating decomposes completely and coke results.

Technically, oils are altered in two ways by heating. The first is the cracking process, where the product required is an oil of low boiling-point which can be used for illuminating purposes, or more recently the object has been to obtain a motor spirit. The other process is pyrogenic, in which the oil is heated to a very high temperature, the object being to completely decompose the oil and obtain oil gas. In the cracking process the object is to obtain as little gas as possible.

After the discovery in America in 1861 of the fact that heavy oil, on being heated, produced lighter oil, many attempts were made to increase the quantities of light oil, and many and ingenious inventions were made.

As early as 1850 Vohl had experimented with mineral oil obtained from brown coal and with heavy Canadian and Pennsylvanian oil, and found that by passing the vapours of these oils through red-hot iron tubes which were filled with iron filings or lime, lighter oils were obtained, together with large quantities of gas. The volume of hydrogen in the gas was very small, unless the tubes were heated to a very

high temperature. Vohl went into the matter very carefully and passed hydrocarbons of known formula, which he isolated from the crude oil, through the heated tubes. He decomposed the hydrocarbons $C_{13}H_{28}$, $C_{14}H_{30}$, and $C_{15}H_{32}$, and obtained from these the hydrocarbons C_8H_{18}, C_9H_{20}, and $C_{10}H_{22}$, the yield in every case being about 70 per cent. of the theory. The rest apparently split up into gases such as C_2H_4, C_2H_2, etc. Personally, I am very doubtful as to the yield of these saturated hydrocarbons, because, as a rule, when saturated hydrocarbons are cracked, considerable quantities of unsaturated compounds are produced.

In 1863 Breitenlohner distilled heavy mineral oil and passed the vapour through a red-hot tube. He found that hydrogen was evolved and that carbon was deposited in the tube, showing that he had gone too far in the process of cracking.

In 1871 Thorpe and Young found that by heating paraffin wax under pressure and distilling, fluid hydrocarbons of the methane and olefiant series were obtained. They stated that heating alone, without distillation, did not crack the paraffin wax. On the other hand, Gawalowski has recently (1910) found when paraffin wax, having a melting-point of 45° C., is heated for a long time in an autoclave, that liquid hydrocarbons and gases are produced. The product appears to belong, in the main, to the ethylene and acetylene series, but also contains paraffin and naphthene hydrocarbons.

Friedel and Craft, in 1878, obtained lighter hydrocarbons by heating petroleum oils with aluminium chloride or metallic oxides, such as iron, zinc, or copper; at the same time sulphur was removed. I believe that the experiments were originally carried out with the object of removing sulphur from Canadian oil.

In 1886 Armstrong and Miller obtained, by heating mineral oils to high temperatures, lighter oils, belonging to the olefine, paraffin, and naphthene series.

In 1887 Benton, an American, obtained a patent for "improvements in the methods and means of refining crude and refuse petroleum." In the process, oils were forced under a pressure of 285 lb. or more to the square inch through a series of pipes heated in a furnace, and the products led into a vapour chamber, where the hydrocarbons condensed and lighter oils were obtained.

In 1889, Dewar and Redwood devised an interesting plant for the cracking of oils under high pressure. It consisted of a still and condenser in free communication with each other—that is to say there was no valve between them—the space above the liquid in the still being filled with air, carbon dioxide, or other gas which was pumped in under the desired pressure. The condenser was provided with an outlet by means of which the condensed liquid could be run off. With this apparatus intermediate and heavy oils could be converted into oils suitable for lamps, and also for lighter oils which at that time had not much value except for carburetting gas. It is interesting to note that this process, with very slight modification, has been re-patented in the United States by Mr. Barton, and is being worked on a very large scale. I understand something like 25,000,000 gallons of light oil are being manufactured annually, or at any rate plant capable of doing so has been or is being put down.

Before describing the present-day processes it will be as well to examine the theoretical pinciples which underlie the cracking of oils, at least so far as we at present understand them. All chemical processes of breaking down under the action of high temperature or of condensing or polymerising are difficult to follow; they appear to be partly chemical and partly physical.

From the technical standpoint the object of cracking is to produce, by means of heating, oils of a lower specific gravity, boiling-point and flash-point. Generally speaking, intermediate oils are employed; that is to say, those which are not suitable either for illuminating or lubricating purposes. Raw oils containing asphaltic products are generally not satisfactory, as they block up the tubes of the apparatus with deposits of carbon, and excessive quantities of gas are obtained. Under ordinary conditions, as already mentioned, most hydrocarbon oils, when distilled under normal atmospheric conditions, commence to decompose between temperatures of 200° to 250° C., but with some oils decomposition commences even lower. The boiling-point of the hydrocarbons increases with the number of carbon atoms contained: the larger the chain, therefore, the greater the tendency to break down. For example, in the methane series heptane C_7H_{16} boils at 98° C. and distils without decomposition. On the other hand, pentadecane $C_{15}H_{32}$ distils at 270° C., but is always more or less decomposed. The following are the formulæ for these two substances—

(1) $CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.CH_3$

(2) $CH_3.CH_2.CH_2[CH_2]_9CH_2.CH_2.CH_3$.

Unsaturated hydrocarbons break up much more readily than saturated hydrocarbons. For example, in the olefine series normal heptylene C_7H_{14} boils at 95° without decomposition, but undecylene $C_{11}H_{22}$ decomposes when distilled at atmospheric pressure; to distil it without decomposition it is necessary to distil under reduced pressure. The unsaturated compounds break up where there is a double bond, or in the case of the acetylene series at the treble bond. The position of the bond varies, and may be at the centre of the chain or at the end. For example—

(1) $CH_3.CH_2.CH = CH.CH_2.CH_3$

(2) $CH_2 = CH.CH_2.CH_2.CH_2.CH_3$.

The naphthenes or saturated ring compounds are not so readily decomposed as the olefines; but those which have a four ring are more easily split up than those with a five ring. Thus, (1) will break up at a lower temperature than (2).

$$(1)\ \begin{array}{c} CH_2 - CH_2 \\ | \quad\quad | \\ CH_2 - CH_2 \end{array} \qquad (2)\ \begin{array}{c} CH_2.CH_2 \\ | \\ CH_2.CH_2 \end{array}\!\!>\!CH_2$$

As oils from different localities contain these different hydrocarbons in varying proportions, it follows that cracking processes will require to be modified for dealing with oils from Russia, America, Roumania, etc.

While, however, unsaturated hydrocarbons are more readily decomposed, they also more readily condense together or polymerise to produce heavier hydrocarbons. This may be an advantage or disadvantage. If very light hydrocarbons, particularly gaseous hydrocarbons, condense together, heavier but still light oils may be produced which may be of commercial value. If, however, the heavier oils condense together, asphaltic or resinous products will be obtained. In most cracked oils, products of a more or less siccative nature are produced which require to be eliminated if the oil is to be used for motor engines, because they have a tendency to gum up the valves. These oils appear to belong to the terpene series of hydrocarbons, and when separated form drying oils, which it is said can be used as turpentine substitutes. Their drying properties are, however, doubtful.

In the cracking process the object is to break up hydrocarbons of high molecular weight into hydrocarbons containing fewer carbon atoms. The endeavour is so to carry out the operation that liquid hydrocarbons are produced, and polymerisation and formation of asphaltic products prevented. It may be said that almost invariably small quantities of actual carbon are produced, which means that a small part of the oil is completely decomposed into carbon and hydrogen. It does not follow, however, that any considerable quantity of hydrogen will be found in the uncondensible gases, because a portion of it will unite with the more unsaturated of the oils which have been produced. When very heavy oils are dealt with, carbon formation invariably takes place. If the oils contain phenolic bodies, that is, oxygenated compounds, there is sure to be asphaltic formation, and ultimately carbon deposited. Many crude oils contain considerable quantities of asphalt, and it is very doubtful whether it would ever be a paying proposition to pass them through a cracking process without a previous distillation to remove the asphalt. In doing this, first, the light fractions would be taken off, which would be refined in the usual manner; then the intermediate oils, which would be subjected to cracking; and, finally, the lubricating oils, if they are present, should be worked up separately.

Probably it is not possible to represent by chemical equations the actual reactions which occur when the oils are cracked. There are so many physical conditions which have to be accounted for—temperature, pressure, velocity of reaction and many others, such as difference of heat at different parts of the system. Imagine, for example, a gas passing through a tube the sides of which are heated to 600° C. Those portions in direct contact with the side will be heated to a higher temperature than the central core, and therefore will be more decomposed. Here speed of action will have an appreciable effect. If the vapour of the hydrocarbon is rapidly forced through, the central core may remain only slightly acted upon; if, on the other hand, the progress through the system is slow, gas diffusion may bring all the gas molecules into contact with the heated surface. The difficulty here is that slow rate of speed means small output. The technologist has to consider and ascertain by actual experiment the speed of passage which will give the greatest yield of cracked oil on the original oil employed, also the smallest gas and asphaltic formation.

According to Thorpe and Young, one may suppose that an oil having the formula of $C_{20}H_{42}$—that is, a saturated hydrocarbon—will, on being strongly heated, either at ordinary atmospheric pressure or under increased pressure, split up into C_5H_{12} and $C_{15}H_{30}$, that is, into a molecule

of a saturated and a molecule of an unsaturated hydrocarbon. Thus—

$$C_{20}H_{42} = C_{15}H_{30} + C_5H_{12}.$$

Such a reaction takes no account of hydrogen gas formation, which is invariably produced in greater or less proportions. The actual product obtained is a mixture of several hydrocarbons of the paraffin series, several hydrocarbons of the olefiant series, sometimes acetylenes, also naphthenes, terpenes, and aromatic hydrocarbons.

Suppose that a hydrocarbon of the ethylene series is cracked and splits across the double bond. For example —

$$CH_3.CH_2.CH=CH.CH_3,$$

we shall obtain $CH_3.CH_2.\underset{|}{\overset{|}{C}}H$ and $\underset{|}{\overset{|}{C}}H-CH_3$, two radicals which could not exist alone. There are here several possibilities, *e.g.*, $>CH.CH_3$ may unite with another similar group and form $CH_3.CH=CH.CH_3$, or two of the heavier radicals, $CH_3.CH_2.CH$, may unite together to form $CH_3.CH_2.CH=CH.CH_2.CH_3$, a heavier molecule, or the hydrogen which is produced probably by the decomposition of a hydrocarbon of the methane series will unite with either of these parts and form hydrocarbons of one or other series, thus --

$$CH_3.CH + 2H = CH_3 - CH_3.$$

These few examples will show how difficult it is to build up a theory which will be of use in the practical working out of a cracking process. Undoubtedly decomposition and reunion of different parts of the oil molecule play a very important *rôle* in cracking processes.

There are a variety of cracking processes which are, or have been, worked on a semi-commercial scale, and they all have essential differences, and there seems no reason why several of them should not be worked successfully. In the long run commercial success will rest with the process or processes which can produce a marketable spirit at a low cost. A certain amount of popular prejudice as to the smell of the oil will have to be overcome. Most of the older brands of motor spirit consist in the main of saturated hydrocarbons, but the cracked spirits have a different odour because they contain other hydrocarbons. One often hears of odourless motor spirit: such a product has not yet been obtained, and probably never will be. Most cracked spirits have a higher calorific value, and will therefore give a greater mileage per gallon than the more well-known brands. I believe that there is a great future before motor spirit obtained by cracking processes; but it is essential, if any process is to be a success, that a guaranteed output can be obtained and that the product is always up to sample.

I will now describe some of the more important processes.

In the Noad process, patented in 1909, the oil to be converted and water are sprayed into a heated chamber packed with scrap iron, from which air is excluded. The chamber is heated to a temperature of about 900° F., and it is claimed that the oil and water are vaporised or dissociated in the process in presence of each other and of the highly heated iron which acts as a catalytic agent. The resultant vapours are condensed, and the liquid products so obtained are rectified to separate the volatile spirit.

The proportions of oil and water required to obtain the most satisfactory results are said to depend upon the particular oil under treatment. Thus, for example, with American Solar Oil having a specific gravity of 0·868, two parts of oil and one part of water are used. After rectification the higher products are again passed through the cracking chamber.

This process has been worked upon a commercial scale by the New Motor Spirit Company at Silvertown. Certain difficulties, however, were met with. The oil had a very unpleasant odour which no known method of purification would remove economically. It was also found that the sulphur in the oil acted upon the walls of the cracking chamber and caused them to corrode. For these reasons the process has not turned out a commercial success.

Lamplough's process is based on a somewhat similar principle, the intermingling of water vapour and oil and passage over a heated catalyser. In this case, however, the water vapour and oil are introduced in the form of steam and vaporised oil under considerable pressure, which is maintained while the mixed vapours are in contact with the vaporiser. The catalyser is nickel, and is placed in the cracking tubes in the form of spirals, thereby causing the vapours to take a spiral path through the system; thus greater contact of oil vapour and steam with the catalyser is obtained. The tubes are heated to redness, and it is claimed that the nickel acts as a catalysing agent.

Sabatier has shown that when oil vapours and hydrogen are passed through heated tubes containing reduced nickel, combination takes place, and saturated hydrocarbons can be

obtained from unsaturated hydrocarbons. It is very doubtful whether massive nickel, such as is used in the Lamplough process, will have the same effect. It is more probable that the cracking is produced by the passage of the vapours through hot tubes, which, owing to their form, give long contact with the hot surface. Pressure may also play an important part.

In all cracking processes in which steam and oil vapour are caused to circulate together, the claim seems to be that the water vapour is decomposed into hydrogen and oxygen, and that the hydrogen acts reducingly on the oils which, owing to decomposition (cracking), are in an unsaturated condition. What happens to the oxygen is not explained, but one might expect the formation of phenolic bodies. In the Noad process the oxygen would—supposing the steam to be decomposed—unite with the iron catalyser to form oxide of iron. I doubt, however, whether the temperature employed by Lamplough would be sufficient for the oxygen to react with the nickel. Moreover, as water only decomposes to a very slight extent at 1000° C., and the temperatures employed in these cracking processes are not much above 600° C., if as high, it is extremely doubtful whether water has any effect except to help to carry the oil through the system.

A method of an entirely different nature, in which no water vapour is employed, is that of Mr. Carter White, which is known as the Carter White process. In this process the oil is allowed to drop or is sprayed into tubes which are packed with lime and are heated to a dull red heat, or a higher temperature if desired. The required temperature, it is found, varies with the nature of the oil dealt with. The oil is vaporised and passes in the form of gas through the tubes, which may be horizontal or vertical. As the vapour passes forward it comes in contact with the heated lime, and a portion at least of the vapours actually passes through the pores of the lime. That the vapours pass through the lime can be demonstrated by breaking up the lime blocks which have been removed from the cracking tubes. They are found to be black throughout, that is to say, carbon has been deposited in the pores of the lime, which could only happen by the vaporised oil passing through the material.

Very heavy and crude oils have been experimented with in this process, and from these a light spirit has been obtained. Like most other cracking inventions, the process is designed to work continuously. That is to say, the heavy oil is passed through the tubes in the form of vapour. A portion becomes cracked, and a light oil results. The light oil is distilled off and the heavy residue is again passed through the system, and so on until no oil remains behind. As a matter of fact, the usual practice is to make up the loss with fresh oil so that there may be no break in the operation. One advantage in the employment of lime is that if the oil contains much sulphur a considerable proportion is removed, so that the final product is relatively free from this objectionable impurity. Cracked oils containing even comparatively small quantities of sulphur have an unpleasant garlic-like odour.

In the original process of Valpy and Lucas the heavy oil to be cracked was passed over a heated spiral or grid. The oil was either atomised or introduced in a state of vapour by preheating. The spiral or grid was contained in a tube from the sides of which it was insulated. An electric current was then passed which heated the spiral to any desired temperature, the electric current being regulated accordingly. Apparently the electric heating was difficult, because in a second patent specification it was stated that electrical heating is not necessary.

The method now employed by Lucas is to pass the vapours of oil and water over a granular catalyser. The catalyser consists of an alloy of iron and manganese, a small addition of certain other metals being found advantageous. The catalyser is porous and absorbs oil with great avidity. The plant consists, in the main, of a still for vaporising the oil and the tubes in which the catalyser is contained. Small quantities of steam may be passed in with the oil vapour. It is not claimed that the steam exerts any chemical influence in the cracking. It is indeed stated in the patent specification that the steam appears at the end of the operation as steam or water, and merely acts as a mechanical conveyer.* The oil vapour and steam pass through the tubes containing the catalyser. The oil vapour will, if the catalyser be well packed into the tube, penetrate its porous structure, and here it is claimed that the chief cracking reaction takes place. There appears to be very little deposition of carbon, otherwise the pores would become rapidly closed up; and I understand that the catalyser lasts a very long time without renewal, and that it can

* The use of steam has now been abandoned.

be made active again by heating and burning off any carbon formation. A large number of alloys were tried before the particular one now employed was arrived at, and the method of making it so as to obtain a porous material also required a large amount of experiment.

The Barton process has already been referred to when dealing with the historical aspects of the subject. It is really an adaptation of the Dewar-Redwood patent of 1882. Thirty years ago light spirit was not required as it is to-day. Illuminating and lubricating oils were those which were sought after. Consequently processes, however ingenious, for cracking oils and obtaining very low boiling products were hardly likely to become a commercial success. For vaporising and cracking oils under pressure, the patent of Dewar and Redwood must be considered the master patent, and it is difficult to understand the granting of a patent to Mr. Barton which in all its essentials is similar to the one taken out in 1882. Be that as it may, oil which was a drug on the market is cracked by distilling it at high temperatures under pressure, the still and the condenser both being maintained under the same pressure. This undoubtedly causes the very low unsaturated hydrocarbons to unite together to produce light oils. I understand that the oils themselves are rather too light, but that when mixed with oils that are slightly too heavy a very useful motor spirit is obtained. The process is worked in the United States by the Standard Oil Company.

In the Hall process we have a totally different principle. No catalyser is employed. The distillation is carried out under pressure, and then the pressure of the vaporised oil is released. The Renard process is on still other lines: the actual cracking is done under pressure, and the pressure is of such a degree that the oil during the whole of its passage through the cracking apparatus is kept in the liquid condition—that is, the pressure is kept higher than the vapour tension of the oil at any given pressure.

The plant of the Petrol Process, Ltd., is worked on somewhat similar lines to that of the Renard process. The oil to be cracked is pumped under a pressure of forty to sixty atmospheres through a series of tubes which are heated to a high temperature. The temperature must not, however, be sufficiently high to vaporise the oil, which is kept in the liquid condition throughout the process. After passing through the cracking chamber the hot oil circulates through closed tubes, contained in a boiler, which are surrounded by water. A portion of the heat is here given up, and by keeping a certain head of steam on the boiler the amount of heat given up can be regulated. After passing through the boiler it is suddenly expanded into a chamber and thus becomes vaporised. The chamber is fitted with a dephlegmator, and here various fractions can be drawn off. The oil, stripped of most of the light spirit, is then siphoned into a still fitted with a steam coil where any remaining spirit is distilled off. The gases are scrubbed and then led under the cracking chamber where they are burnt. The unchanged oil is passed back to the storage tank and again circulated through the system, the loss from conversion being made up with fresh oil.

In the Hall process the oil is passed through coiled iron tubes, which are heated to a temperature of about 600° C. This temperature, being much above the boiling-point of the oil, causes a pressure within the system. The oil is continually pumped against this pressure. The hot vapour is held back by means of a check valve. Here it is allowed to pass into a tube, from which the vapours are caused to impinge against a baffle plate contained in an iron cylinder 12 to 16 in. in diameter and about 12 ft. high. This is the actual cracking chamber. So much heat is developed at this stage that the oil becomes cracked. It is then allowed to pass slowly up the chamber, and then through two or more dephlegmators.

When the oil decomposes, or cracks, a certain quantity of free carbon is produced, which ordinarily is very difficult to remove from the oil vapour. The cracking chamber above the baffle plate is packed with pieces of iron tube about 1 to 1½ in. long. These present a very large surface, and the carbon deposits on them in a nodular form. From heavy oils containing much asphalt very much more carbon is produced than from lighter oils, such as solar oil.

The oil is circulated very rapidly through the heated tubes, and when the pressure is released at the check valve the vapour which is produced passes forward at great velocity and strikes the baffle plate with great force, the velocity being immediately brought to zero. The temperature here rises considerably, and this points to an endothermic chemical reaction, because when a gas expands lowering of temperature is the general rule. To a certain extent the oil is completely decomposed, and carbon is produced which adheres to the iron tubes already mentioned. The bulk of the oil is broken down into lower boiling fractions and a portion passes

forward unchanged. The heavy oil is separated by the dephlegmators which are not water-cooled. The light oil and gases pass forward through a settling chamber which removes any entrained oil, and then to the compression pump. The gases and light fractions are here subjected to compression. At this stage a further chemical action appears to take place, which is evidenced by the increase in volume of the liquid. That actual union of the gases with the light fractions, or of the gases with one another to form liquids, takes place is shown by the fact that on fractionation very little gas is evolved. This shows that it is not a question of gas solution in the light oil, but actual conversion of the gas hydrocarbons into liquid hydrocarbons. The spirit can, in fact, be several times redistilled without alteration in boiling-point. This would not be the case if it contained gas in solution.

Light oils obtained by the cracking process always require a certain amount of refining by treatment in the usual way with sulphuric acid and alkali. They generally contain small quantities of turpene-like bodies which are of a siccative nature. If these are not removed they cause gumming in the valves of the automobile engines. Owing to cracked oils containing larger quantities of unsaturated hydrocarbons, and therefore having a higher carbon content than uncracked oils, the calorific value is slightly higher than natural light oils, and consequently the mileage per gallon of spirit is also a little higher.

Cracked spirits have a different odour from natural spirits, and for this reason there has been rather a prejudice against them. It is not that the smell is unpleasant, but that it is different to that which the public has been accustomed to. When, however, these oils are manufactured on a larger scale, no doubt this prejudice will die down, and there appears to be a great future for cracked oils.

The problem of satisfactorily cracking oils to produce light spirit has been worked at for many years, and the difficulties have one by one been surmounted, so that at present there are several processes which may be said to have solved the difficult problem.

BIG CREEK HYDROELECTRIC WORKS.

The Big Creek, a tributary of the San Joaquin River, is a mountain torrent that dashes down the Sierra Nevadas about seventy miles east of Fresno, California. So precipitous is its course that it drops some 4,000 ft. in six miles; and it carries a copious supply of water, as it drains a basin of 88 square miles, which, with an annual rainfall of more than 80 in., gives a run-off of 50 in. With a plentiful supply ensured and an enormous head, conditions are ideal for the generation of electricity.

A Government permit has been granted to the Pacific Light and Power Company of Los Angeles to develop the power of Big Creek, and some particulars of the enterprise have been given to the *Scientific American* by the Stone and Webster Construction Company, the engineers of the undertaking. Twelve years were allowed for the completion of the work. But with great enterprise the company set a record for rapid work in completing the initial development inside of two years. The first work was to build a railroad fifty-six miles long to reach the site of the development. This road was finished and equipped in 157 days. Then three concrete dams were constructed to close gaps between the ridges bounding the basin in the mountains, thus making the reservoir 7,000 ft. above the sea, four and a half miles long by half a mile wide, with a capacity of about 53,000 acre-feet. The capacity will later be increased to 120,000 acre-feet by raising the dams 50 ft. higher.

The fall of 4,000 ft. has been utilised by leading the water through a tunnel and steel pipe lines to the first power-house half-way down, and then through another tunnel and series of conduits to the second power-house. Driven by this mighty head, the water rushes out of the 6-in. nozzles at the power-house with a velocity of 350 ft. per second, which is about 240 miles per hour. The jets dash across an open space of a few inches and then strike the buckets of the impulse wheels, which spin round as fast as the drivers of an express locomotive travelling 100 miles per hour. These wheels are 94 in. in diameter and are arranged in pairs, each pair developing 23,500 horse-power. Despite the enormous velocity of the jet, there is no shock at the impact with the water wheel, because the part of the bucket first touched is nearly parallel with the jet.

After passing through the first power-house the water discharges into the creek. But the creek is here blocked by another dam, and the water is diverted through a second tunnel four miles long into a second series of steel conduits leading to the second power-house.

In each power-house there are two main generators of 17,500 kilowatts capacity each. Here the current is generated at 6,600 volts and raised by transformers to 150,000 volts. The current is carried to Los Angeles, 240 miles away. Two lines of steel towers on a right of way 150 ft. wide will carry six cables, an inch in diameter, from the two power-stations to a sub-station at Eagle Rock, in the suburbs of Los Angeles.

In less than a year and a half after the work at Big Creek was begun both power-stations and one transmission line were in operation, and current generated at Big Creek was in commercial use at

Los Angeles. This involved the setting of more than 3,000 steel towers over the mountains and across the desert and the stringing of nearly 5,000,000 lb. of aluminium cable. It is interesting to note that, by virtue of the great elevation of the reservoir above the two power-plants, every cubic yard of water it contains is worth from 10 to 20 lb. of coal to generate one horse-power in a steam-plant. When the full possibilities of the Big Creek development are realised it will form an inexhaustible mine of energy with an output that could not be equalled by the consumption of over eight million tons of coal per year in a very efficient power-plant.

RUSSIAN COTTON CROP OF 1914-15.

According to a report by the U.S. Consul-General at Moscow, a bulletin issued by the Russian Central Cotton Committee contains the following estimate of the area sown to cotton and the production of pure fibre in Central Asia and Transcaucasia for 1914–15, with comparative figures for the preceding season:—

District.	1913 14.	1914-15.	Production.	
	Acres.	Acres.	Bales of 500 lb.	Bales of 500 lb.
Ferghana	739,473	776,011	548,994	607,515
Samarkand	85,429	96,369	68,826	72,200
Bokhara	177,540	177,540	105,152	119,163
Transcaspia	122,965	151,740	62,759	69,765
Khiva	69,940	69,940	49.593	46,943
Syr-Daria (not including Amu-Daria)	182,428	198,831	80,670	88,686
Erivan Province	102,220	107,600	49,555	43,330
Elizavetpol	134,500	142,570	47,305	45,934
Baku	53,800	75,320	12,345	25,277
Tiflis	13,450	14,795	4,226	5,778
Kutais	5,380	5,380	722	1,084
Total	1,687,125	1,816,096	1,030,147	1,125,675

Of the 607,515 bales of cotton harvested in the Ferghana district, about 70 per cent. will probably be first grade, 15 per cent. "minus," 10 per cent. medium, and only 5 per cent. of the second and third grades. The total crop of clean fibre in Turkestan is estimated at 1,004,272 bales, against 915,994 bales obtained in 1913–14, an increase of about 10 per cent. The crop of cotton fibre in Transcaucasia is expected to amount to 121,403 bales, as compared with 114,153 bales in 1913-14.

The Central Cotton Committee expresses the opinion that the probable crop of Russian cotton cannot but have a reassuring influence on the cotton manufacturing industry at this time of urgent need of raw material. The committee calculates that on September 1st, 1914, the supplies of cotton in the country amounted to 433,520 bales, and 144,400 bales were imported from Asia (Persia, etc.). If to this quantity be added the 1,125,675 bales of cotton produced in Central Asia, the total amounts to 1,703,595 bales. Calculating that the total consumption of cotton in Russia (excluding the Lodz district) does not exceed 1,444,000 to 1,516,600 bales of fibre per annum, the committee believes that the Russian factories will not have to be closed, even if no shipments of American cotton should be received until September 1st.

IRRIGATION IN INDIA.

The official review of irrigation in India during the year 1913-14 has recently been published. The interest earned in the case of "productive" canals was nearly 9¼ per cent., the acreage irrigated being 16,320,000. Minor works for which capital and revenue accounts are kept earned 4·39 per cent., and even purely protective works 1 per cent. As the last-named only serve about half a million acres they are not of much account. It is in connection with the value of crops raised on irrigated areas that the full benefits of the canals are seen; that value was 8½ crores of rupees, the bulk being of course in the Punjab (2,645 lakhs), with 1,831 lakhs in Madras and 1,590 lakhs in the United

Provinces. In the years to come the Punjab will show much bigger figures, as the triple canal project has practically been finished; and in the other two provinces also there will be expansion as new works are being undertaken on a large scale. The Punjab must always remain the premier province in the matter of canals, as it has already between seven and eight million acres under irrigation, and the return on capital is over 15 per cent. In 1913-14 the Lower Chenab Canal had a net revenue which gave over 42 per cent. on capital outlay, the Lower Jhelum Canal coming next with nearly 21 per cent. Madras has the satisfaction of getting a return of 13¼ per cent., but the United Provinces have to be content with just over 8 per cent., and Sind with about 5½ per cent. on productive works. The year under review was marked by intense drought in the United Provinces, both in the *kharif* and the *rabi*, and the resources of the canals were taxed to the utmost. They could not be closed as the demand was continuous throughout the year. Nearly a million acres more than the annual acreage were irrigated, and it became clear that in Bundelkhand the existing sources of water-supply were quite insufficient to meet requirements in seasons of drought. The necessity for additional storage for the Betwa, Dhasan and Ken canals is dwelt upon in the official review. The lesson learned from the drought of 1913 14 cannot be ignored; it is now known that when the monsoon gives fitful and deficient rainfall, and the winter rains are also in defect, the three canals mentioned cannot save the crops in the areas which they serve. Increase in storage is needed, and this improvement must be made before the recurrence of another drought.

TRADE OF THE STRAITS SETTLEMENTS.

By G. d'Almeida.

The "Appendices to the Report on the Trade of the Colony for the year of 1914" contain some most interesting figures on the oversea and internal trade of the Colony and adjoining States, from which it appears that, notwithstanding the disruption of business generally, the Colony has not suffered as much as might have been expected under the circumstances.

Thus during the year of 1914 the grand total of exports of the Straits Settlements amounted to $334,126,020, against $388,929,705 during 1913. This shows a falling-off of $54,803,685, or £6,393,763. The imports during 1914 were $391,373,123, or £45,660,197. The decrease amounts to $88,082,355. In imports the Colony totalled $391,373,123 in 1914, on which the various parts of this Colony share as follows: Singapore, $280,430,001; Penang, $106,739,526; Malacca, $3,433,381; Labuan, $639,215; and Christmas Island, $131,000 = $391,373,123. Textile goods imported amounted to $34,493,442, against $48,592,077 for the previous year. Metal values totalled $13,521,492, and miscellaneous goods reached the figure of $19,278,093, against $24,834,869 for the past year. The total value of imports into the Colony was thus $375,907,564 in 1914, against $454,376,239 during the year 1913. This applies to manufactured or partly manufactured goods.

In raw materials the local trade also showed a decrease in volume and value. The total for 1913 amounted to $188,333,981, against a sum of $156,364,785 for the period under review. This latter figure is composed of textiles, $807,510; metals, $81,566,907, and other goods, $73,990,368. Last year's figures were: Textiles, $1,620,986; metals, $109,229,606, and $77,483,389 for miscellaneous goods. These figures cover foreign imports only.

Imports.

The effects of the war are also noticeable in the export trade figures, which show a total of $331,126,020, against the 1913 figure of $388,929,705. These totals for 1914 are computed from the following. Live animals, foods, drink, and narcotics, $117,634,888 ($132,908,249 for 1913). Raw materials: Textiles, $667 071 ($1,485,902 for 1913); metals, $86,201,194 ($83,627,497 for 1913). Total, $172,880,770 ($198,851,404 for 1913). As far as the manufactured goods are concerned the figures work out as follows:—

Textiles	1913 . .	$19,961,206
	1914 . .	$16,716,856
Metals	1913 . .	$6,489,790
	1914 . .	$5.542,338
Other	1913 . .	$14,732,619
	1914 . .	$13,214,034
Total	1913 . .	$41,183,615
	1914 . .	$35,473,228

Coin and bullion were exported to the total value of $8,137,134, against $15,986,437 in 1913.

The total trade with the various portions of the Colony by rail amounted to: Imports, $17,948,000, against $13,421,000 for the previous year; exports: 1914, $9,835,000; 1913, $11,324,000.

Australia and New Zealand.

The total value of the exports to Australia and New Zealand was $1,600,000 in 1914, while the imports totalled $8,081,000 during the year. This also shows a drop, the 1913 figures being $1,853,000 and $735,000 respectively.

British India and Burma.

The imports during 1914 totalled $34,276,000, against $48,813,000 for the previous year. Exports show the following figures: $16,270,000 for 1914, against $17,746,000 for the past year.

Japan.

Our trade with Japan shows only a slight decrease during the past year. The imports were well maintained with $12,092,000, against $12,898,000 during the previous year; the exports to the Island Empire, however, dropped from $5,429,000 in 1913 to $3,517,000 in 1914.

SIAM.

There is an increase in the value of padi and rice, the amount of value of the former being $1,754,000 in 1914, against $1,273,000 in 1913; and for rice, $25,846,000 in 1914, against $24,538,000 in 1913. Otherwise there has been a general decline both in export and import items.

FEDERATED MALAY STATES.

The Federated Malay States have also experienced a falling-off in import and export values—in fact, the total export and import figures have decreased to the amount of the 1911 figures.

There has been an increase of copra export ($1,369,000 in 1913 to $1,797,000) in the period under review; but against this there was a falling-off in import values. The imports for 1913 totalled $101,231,000, against $78,535,000 for the year under review. There was a decrease of $22,696,000 in imports, and a falling-off in the value of exports of $11,854,000.

NETHERLANDS INDIES.

For the year under review a total of $57,426,000 was reached for import values, while the exports dropped to $45,531,000 for the year 1914. The figures of 1913 show sums of $69,638,000 and $49,427,000 respectively. The decrease has largely been due to the restrictions in the export of sugar ($10,381,000 for 1913 to $7,600,000 for 1914) and rattan ($4,164,000 for 1913 to $2,243,000 for 1914), rubber, gutta-percha, and jelutong having also fallen considerably. The decline in values in the Netherlands Indies trade is general, there not being a single commodity of importance which has maintained its previous year's figure. Owing to the war, manufactured goods have been showing only nominal increases.

HONG-KONG AND CHINA.

From a total of $39,888,000 in 1913, import values fell to $32,130,000 in 1914, while the export figures also show an important decline from $15,195,000 in 1913 to $10,770,000 for the period under review. A large decline in the figures of sugar ($1,584,000 to $215,000) is the only notable drop in the figures of import and export, the falling-off being general. The total decreases of our trade with China and Hong-Kong are: Imports, $7,758,000; exports, $4,425,000.

INDO-CHINA.

Both imports and exports from this Colony have been maintained on a fairly normal level. Imports are valued at $16,510,000 for 1914, against $14,959,000 for 1913, this being an increase of $1,551,000. The exports show $2,157,000 ($2,917,000 for 1913), a decrease of $760,000 for the year. The increases are in rice, cattle, and sugar.

MALAY PENINSULA.

Johore, Kelantan, Trengganu, and Kedah.

These States have fairly well maintained their trade, the total combined figures having dropped only from $29,255,000 in 1913 to $28,562,000 in 1914. The Para rubber figures show an increase of $2,415,000 (from $2,227,000 in 1913 to $4,642,000 in 1914). In the export figures there are but slight variations from last year's figures, though there was a general decline.

BRITISH NORTH BORNEO AND SARAWAK.

Exports for 1914 were $4,606,000, against $5,860,000 for 1913, a decrease of $1,687,000 (1913), $5,718,000, a decrease of $1,031,000. Here also the figures show that the falling-off in exports and imports has been general.

When the whole of the Colony's trade during the past year is considered it must be admitted that, notwithstanding this disastrous war, the Colony has well maintained its place in the world's markets.

ARTS AND CRAFTS.

National Competition in War-time.—It is remarkable how little effect the war seems to have had on the quantity and the quality of the works sent up for National Competition. It comes at first as somewhat of a shock to see how much this year's exhibition resembles those of previous years. An examination of the labels attached to the exhibits, however, shows that the great majority of the male exhibitors are engaged in some definitely useful trade or craft, and are not art students by profession, whilst the catalogue reveals how large a proportion of the successful students are women. Again, in certain sections, notably metalwork, there is a considerable falling-off in the number of works sent up. It is, perhaps, to be regretted that in some respects, at any rate, the war has not made more difference to the competition. It would obviously be a bad thing for art education to be in any way curtailed, especially at a time when our enemies are also our great commercial rivals and we have to be ready to show ourselves masters not only in arms but in more peaceful arts. On the other hand, we are face to face with a great national crisis; we are spending liberally and lavishly on those things which are for the moment essential to our national well-being, if not to our existence as a nation, and it seems highly improbable that in anything approaching to the near future the country will have much money to spend on anything but necessities; yet both the works exhibited and the reports of the examiners go to prove that the art schools of the country, and the students who fill them, are still very largely occupied with the production of luxuries.

The various exhibitions held in London and elsewhere, under the auspices of the Board of Trade, have demonstrated, at any rate, the important part which design plays in manufacture and commerce—even from the strictly utilitarian point of view—in ordinary times and under normal conditions. The demands of expenditure for national purposes will probably increase to such proportions that the majority of those who under

ordinary circumstances could afford hand-made and expensive goods will have to content themselves with manufactured articles. It seems as though, in the years that are coming, if industrial art is to flourish at all, if it is to be able to make its appeal to any substantial number of people, if it is to have any real influence, it must perforce express itself mainly through manufacture. And yet over and over again we hear the same tale. The designs for wallpapers are so poor that the highest award the examiners can see their way to make is a book prize. In woven textiles they regret that "they are not able to report an improvement in the standard of work." In damasks "the standard of merit . . . is not so high as that of last year," and these adverse criticisms on large classes of work are by no means compensated by slight improvements in such relatively small sections as carpets and linoleum. Of the seven gold medals only one is awarded for an object to be reproduced by any mechanical or manufacturing process, and that is for a "lace flounce"; while of the fifty-four silver medals only ten, on the most liberal computation, go to designs for reproduction or for any kind of manufacture.

This is a position of affairs which appears to go to show a want of recognition of the needs of the moment. It would be wrong, of course, to allow crafts in which we as a nation excel to languish unnecessarily—they are bound at times like this to be in more or less evil case—but for the moment and in the immediate future, at any rate, our best energies in the domain of art ought to be directed towards increasing our industrial efficiency. We have of late been producing craftsmen rather than designers; if after the war there is any demand for highly trained art workers at all, it will be for designers rather than for craftsmen, and it is to be regretted that the best and cleverest of our students seem still to be turning their eyes in the direction of individual self-expression rather than towards providing tasteful and beautiful things to be used by the greatest possible number of their fellow-countrymen.

It is, however, cheering to see that the designs for pottery, tiles, etc., are better this year than usual. Pottery is one of our large export industries which we may hope will flourish with renewed vigour when the war is over. Further, it must be remembered that the work of the schools was in large measure planned last year before the war broke out, and readjustment takes time. It is to be hoped that in the coming session design will absorb the energies of the larger proportion of the students.

Studies, Designs, and Various Crafts at National Competition.—If we turn to the several subjects, we find that as usual there are some discrepancies in the awards and that certain groups of examiners have been far more generous than others in distributing medals, prizes, and commendations. It really is a pity that no general revision of the successful works as a whole is attempted, for it is impossible to expect small committees of men acting independently to set before themselves exactly the same standard, whilst if they saw the prize designs of their own section exhibited along with those of other groups, they would perceive at once that there had been some difference in their demands.

Of the subjects more or less preparatory to design it is worth noticing that the studies in historic ornament were on the whole carefully and intelligently chosen for their purpose, but the examiners complain that "some studies . . . suffer from an over-elaboration of painting in useless imitation of what may be called still-life effect," and even some of those to which awards have been made are not as directly and simply treated as they might have been. The studies from nature in preparation for design also reached quite a good level, but the "flower and three designs," which ought to indicate that students know how to use their studies when they have made them, were not only few in quantity, but also bad in quality.

The lettering on the whole is very satisfactory and shows distinct improvement, the typography is adequate and the illumination, though there is nothing of very conspicuous merit, reaches as a whole a sufficiently high level. The tooled bookbindings are rather better than last year, and candidates have at length been found to send in designs for publishers' cases—certainly a step in the right direction. Book illustrations reached much the same standard as usual. Some good lithographic studies were sent up, whilst the posters as a whole were satisfactory—though the examiners report a falling-off in the colour-prints. The designs for glassware are more suited to useful purposes than they have sometimes been. The stained glass as a whole is on right lines, and the design which gained a silver medal exhibited a certain amount of originality as well as a knowledge of glass technique. The jewellery is good both in execution and design, and the enamelling generally shows improvement. Some of the cloisonné from Dublin is really excellent. The embroidery is not on the whole very remarkable, but there is some quite good work, some of which might, perhaps, with justice have received rather more recognition than it has done. The designs for machine-made lace are highly commended by the examiners, and in many cases show far greater regard for artistic treatment than this type of work has generally done in the past. The wood-carving reaches a rather higher standard than usual, and the frame from Manchester to which a gold medal was awarded is a really distinguished piece of work, fresh and dignified in treatment, paying due regard to tradition, but allowing the executant's own personality to appear. Some of the stained wood and gesso is also very good, but one rather wonders how far there is an opening for any large quantity of this kind of work, which has of recent years become quite a feature of the exhibition.

On the whole, this year's show is not only as satisfactory as could have been expected under the circumstances, but not appreciably behind those of more propitious years.

The Exhibition at the Royal College of Art.—Unlike the National Competition, the exhibition of students' work held at the Royal College of Art shows signs of having suffered very considerably from the war. This is easily accounted for by the fact that normally the people who are working at the college are students in the more restricted sense of the term—men and women who are giving their whole time to study—and men in this case have very naturally and rightly responded in large numbers to their country's call. The exhibition cannot, therefore, be judged as a representative collection of the works of the students as a whole: it only shows what has been done by the women and by those men who, for some reason or other, have not joined the army. The students who did such good stained-glass work last year are in His Majesty's forces, and the sculpture, decorative painting, design, etching, and, in fact, nearly all the departments of the college, have suffered—as they ought to have done—from the diminished numbers. It is, however, fair to add that in those crafts, such as embroidery and the design for hangings of various kinds, in which as a rule most of the students are women, the work does not reach quite so high a level of accomplishment as one is justified in expecting of a school of practically university rank.

GENERAL NOTES.

Coal Output of China.—According to the "National Review of China," as a result of a recent investigation, the annual output of coal in the provinces of China is estimated as follows:—

Province.	Output.
Chihli	2,164,000 tons.
Shansi	2,500,000 ,,
Shantung	933,000 ,,
Honan	900,000 ,,
Hupeh	100,000 ,,
Hunan	400,000 ,,
Szechwan	300,000 ,,
Anhui	60,000 ,,
Shensi	50,000 ,,
Kansu	50,000 ,,
Kwangtung	50,000 ,,
Yunnan	30,000 ,,

A New Sewage Treatment.—A novel system of sewage treatment is described by Dr. E. Howard Tripp in the *Journal of the Chemical Society*. The Dickson centrifuge process of separating solids from sludge consists in treating it with 0·5 per cent. of yeast for twenty-four hours at 33° C. Anaerobic fermentation sets free the gases, and the solids rise to the surface, from which they are run off. Brewers' yeast is the most effective agent, but dextrose, starch and certain other substances produce similar results. The sludge is then completely dried by exposure to hot air. The dried material contains 3 per cent. of nitrogen and 50 per cent. of organic matter, and possesses valuable properties as a fertiliser. The centrifuge treatment consists in passing the effluents through a centrifugal machine, the perimeter of which is perforated and covered with a layer of sand. As it passes through the interstices of the sand, a bad effluent is completely oxidised and supersaturated with oxygen; if it be further treated in a small contact bed and again centrifuged, the purification, both chemical and bacteriological, appears to be complete.

"Calorising" Coating Iron and Steel.—It is reported that in the Research Laboratory of the General Electric Company of New York, a new process for placing a protective coating on iron, steel, and other metals has been devised. This is for use especially under high temperature conditions. Calorising, the name given to his discovery by Mr. T. Van Allen, consists of heating metals in revolving drums with mixtures containing, among other things, finely divided aluminium, so that a surface alloy containing aluminium is produced. In the case of copper, this alloy is of the nature of an aluminium bronze, but richer in aluminium than the ordinary alloy of that name and more resistant to heat, so that copper thus treated is protected, up to the melting period of the alloy, from the scaling which occurs when untreated copper is heated above 300° C. The same general result is obtained in the case of iron and steel. Pieces which, because of their shape or size, are not adapted for tumbling, may be calorised by packing them in, or painting them with, a suitable mixture and heating them. There are many places where it is desirable to use iron vessels or apparatus at temperatures above red heat, and at such temperatures untreated iron rapidly oxidises and scales away. After iron is calorised the effect of heating is slight.—*Page's Engineering Weekly*.

Trade in Human Hair.—Owing to the discarding of queues among the male population of Canton and surrounding districts there is, of course, not the same quantity or quality of hair to be had as in previous years. And even though the supply of female hair can be had still, exporters are not inclined to go into the business seriously, because so many small dealers have entered into the trade. It is reported that one or two foreign firms have suffered severely as a result of claims growing out of the fact that the quality has deteriorated so enormously. The export in 1914 was 859,333 lb., valued at $124,117, as against 1,590,933 lb., valued at $356,662 in 1913.

Journal of the Royal Society of Arts.

No. 3,276. VOL. LXIII.

FRIDAY, SEPTEMBER 3, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

PETER LE NEVE FOSTER PRIZE.

Mr. Reginald Le Neve Foster has presented the Society with a donation of £140 for the purpose of founding a prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879.

The Council have determined to offer the prize for a paper on "Zinc, its Production and Industrial Applications."

The prize will consist of a sum of £10 and the Society's Silver Medal.

The paper for which the prize is awarded will be read at one of the Ordinary Meetings of the Society.

It is expected that some account will be given of the history of the metal, the sources of its supply, its metallurgy, and the various uses to which it has been, or may be, applied.

Intending competitors should send in their papers not later than December 31st, 1915, to the Secretary of the Royal Society of Arts, Adelphi, London, W.C.

The paper must be type-written. It may be sent in under the author's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges nothing deserving the full award is sent in.

PROCEEDINGS OF THE SOCIETY.

SPECIAL WAR LECTURE.

FIELD TELEPHONES.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

Delivered July 28th, 1915.

Ninety years ago, in 1825, William Sturgeon, a retired gunner of the Royal Artillery, received from this Society a silver medal and a grant of thirty guineas for his invention of the electro-magnet.* To-day, in this greatest of all wars, the combatants on both sides find that the telephone, an instrument based upon Sturgeon's discovery, is an indispensable adjunct in the conduct of operations in the field. By its aid communication is established between the various units, guns are fired according to orders conveyed by telephone from the battery observer, and in nearly all cases where it is necessary to keep two or more stations in touch the telephone is used. Flag signalling, being too conspicuous, has practically been abolished: and the present war has rightly been termed a "telephone war."

The telephones to which we are accustomed in civil life are unsuited to military operations for two reasons. Firstly, they lack portability; and, secondly, they are not provided with a means of transmitting messages by Morse code in the event of speech being inaudible. It has therefore been necessary to design special instruments for use in the field, and it is to a description of these, and the methods of using them, that the present lecture will be devoted.

Circuit of Field Telephones.

The usual arrangement of parts in field telephones follows on the lines indicated in Fig. 1. The primary circuit consists of a battery, B, connected to the primary winding of an induction coil, P, and to the vibrator or buzzer, V, through the key, V.K. The microphone or transmitter, M, is placed in parallel with the buzzer, and may be brought into the circuit by means of the key, M.K. The secondary circuit consists of the receiver, R, one end of which is connected to line and the other end to the secondary winding, S, of the induction coil, which in turn is joined to earth through a condenser, C. The arrangement at the other end

* *Transactions*, Vol. XLIII. p. 37.

of the line is identical with the foregoing, and to establish communication the operator at either end connects the line to the terminal L, and attaches the terminal E to an earth-pin through S. This current, on passing through the distant receiver, causes a disc to vibrate and reproduce the original sound. It will be noted that the near receiver, being in the line

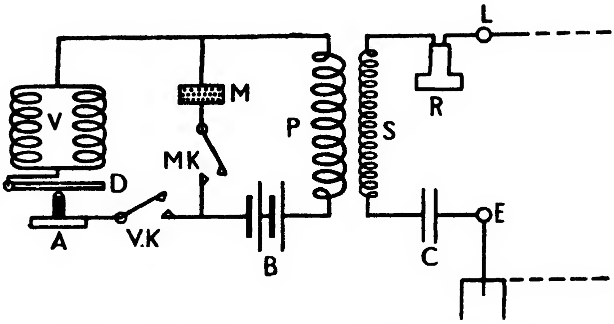


FIG. 1.—TYPICAL CIRCUIT OF FIELD TELEPHONE.

driven into the ground. In different forms of field telephones this circuit is modified in various ways. Most modern instruments possess a third terminal, placed between the condenser and the secondary winding of the induction coil, so that the condenser may be cut out or brought into the circuit as desired. In the Stevens telephone the induction coil serves to operate the buzzer: in the Service instrument, known as the "D Mark III," the buzzer windings perform the functions of the induction coil, and a second receiver, inserted in parallel with the first, is provided. The circuit shown in Fig. 1 may, however, be regarded as the fundamental type upon which the others are based.

Before proceeding to the description of the component parts, the working principle of the telephone may be considered in relation to this typical circuit. When the buzzer is worked, or when a sound wave impinges on the microphone, the current through the primary coil, P, is continually changing in strength. This causes induced currents to be set up in the secondary coil, S, the direction of which depends upon whether the current through P is increasing or decreasing; and inasmuch as the primary current is stronger and weaker in turn, an alternating current is established circuit, will be similarly affected. The greater the change in the primary current, whether increase or decrease, the stronger is the current induced in the secondary circuit, and the louder the sound heard in the receiver.

CONSTRUCTION AND ACTION OF COMPONENT PARTS.

1. *The Battery.*

In the regulation Service telephone the battery consists of two "dry" cells, of external dimensions $3\frac{3}{4} \times 1\frac{1}{2} \times 1\frac{1}{2}$ in., connected in series. The negative plate takes the form of a zinc box, which serves as a container for the other ingredients. Lining the zinc box is a paste containing sal ammoniac, which acts as the exciting material. The positive plate consists of a carbon rod located in the centre of the cell, the intervening space being filled with a mixture of black oxide of manganese, carbon, and sal ammoniac, the first-named acting as depolariser. These cells are issued in the dry state, and must be moistened before use. For this purpose an open glass tube is provided in the top of the cell, into which water is poured according to instructions printed on the side of each cell. After adding the water, eight to ten hours are required before each part has become moist, when the cell is ready for use. When

Operation. Two cells in series used.	Current (amperes).	Useful life of cell.	Final voltage.
Using simple buzzer	0·2—0·3	15 hours	1·2 or less
Using polarised buzzer	0·1—0·15	25 30 ,,	,,
Speaking through microphone . . .	0·2—0·4	12 ,,	,,

fresh these cells have an E.M.F. of 1·5 volts, and in this condition give satisfactory results. Continuous working, however, soon causes deterioration, and when the voltage has fallen to 1·2 per cell it is difficult to transmit messages either by buzzer or speech. Some cells last longer than others, but in the average case the particulars given on page 882 have been found to hold true.

The foregoing figures indicate that frequent renewal of cells is necessary when the telephones are in active use. The best clue to the condition of a cell is furnished by the readings

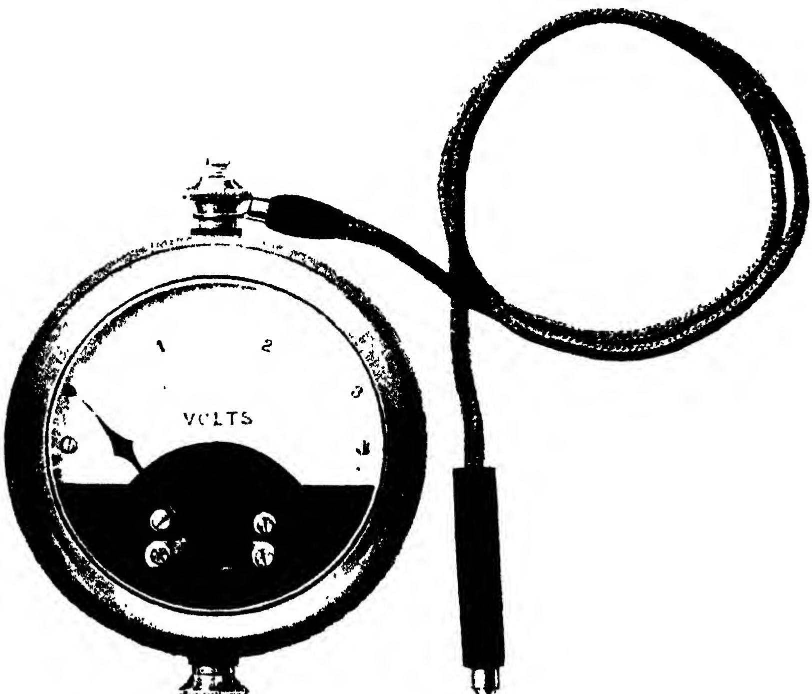

Fig. 2.—Pocket Voltmeter for Use with Field Telephones.

of a voltmeter placed across its terminals, and any cell showing a less figure than 1·3 should be replaced by a new one. Voltmeters used for this purpose should be of the moving-coil pattern, and capable of reading accurately to $\frac{1}{10}$ volt. A satisfactory form, of size suitable for the pocket, is shown in Fig. 2. It is a moving-coil instrument, having a range of 0–3 volts, divided into tenths, and is made by the Stonebridge Electrical Company, Willesden. Failing a voltmeter, the telephonist may deduce the failure of the cells from the weakness of the note of his buzzer.

2.—*The Induction Coil.*

The induction coil used in field telephones is usually 2 to 3 in. long, and possesses a core composed of a bundle of iron wires. Its function is to convert low-pressure currents in the primary circuit into high-pressure currents in the secondary, which travel through the line and receivers. The resistance of the primary winding is about 0·5 ohm when used with a simple buzzer, and about 3 ohms when in conjunction with a polarised buzzer, such as in the "D Mark III." The secondary winding possesses about thirty times as many turns as the primary. The direct currents passing through the primary, which continually fluctuate in strength, produce alternating currents in the secondary and its connections.

3.—*The Buzzer or Vibrator.*

This part of the instrument serves the double purpose of acting as a call-up, and also as a means of transmitting messages by Morse code. In the simple form, the action is identical with that of an ordinary electric bell. Referring to Fig. 1, the buzzer V is seen to consist of two windings, through which the current from the

battery divides. These windings are provided with iron cores (not shown in the drawing), and the path of the current is continued through the iron armature, D, and the adjusting-screw, A. When a current passes through the windings, the cores are magnetised, and attract the free end of D, thereby drawing it away from A and breaking the circuit. The cores then lose their magnetism, and the armature springs back and renews contact with A, thus restoring the circuit. The rapid to-and-fro movement of D gives rise to a buzzing sound, from whence the arrangement derives its name. As the buzzer is in circuit with the primary of the induction coil, every make and break of the current caused by the vibration of D will give rise to an induced current in the secondary, which, passing through the line circuit, acts on the receivers so as to reproduce the note emitted by D. The key, V.K, is used as a Morse key for the purpose of sending messages, a long contact representing a "dash," and short contact a "dot."

The objection to the simple buzzer described, which is used in the Service "D Mark II" field telephone—now becoming obsolete—is that the note lacks sharpness, and is not suited to the rapid transmission of messages. In the Stevens field telephone the core of the induction coil, which becomes magnetised when a current passes through the primary, is used to attract the armature, a plan which simplifies construction by dispensing with the separate buzzer coils. A polarised buzzer, such as will be described later in connection with the "D Mark III" telephone, is preferable to a simple buzzer, as it requires less current to work and gives a sharper note.

4.—*The Receiver.*

For economy of weight and space, the receivers of field telephones are made in the "watch" form. The iron pole-pieces are mounted on a circular magnet, and are wound with coils of combined resistance about 200 ohms. The iron diaphragm, which is set into vibration by the alternating currents circulating round the coils, is held in position by the screw-top of the case, and is prevented from touching the pole-pieces by means of a brass washer round its rim. For convenience of re-wiring, the terminals are, or should be, placed on the exterior of the case.

5.—*The Microphone or Transmitter.*

This part consists of a replaceable capsule contained in a metal case, the top of which screws on to the lower portion, and holds the capsule in position. The capsule contains a carbon block, with cavities in its upper surface which are filled with small spherical granules of carbon. Touching the granules is a carbon disc, protected from moisture by a covering of mica. When in use the current from the battery passes through the granules, and when the carbon disc is vibrating, the area of contact at this part of the circuit is constantly changing. This results in changes in the strength of the current, and, as the primary of the induction coil is in the circuit, induced currents are produced in the secondary and its connections, which cause the diaphragm of the receiver to vibrate in unison with the disc of the capsule.

6.—*The Condenser.*

Although not essential to the transmission of sounds, a condenser, inserted in the line circuit, is a useful adjunct to a field telephone. It is made up of alternate sheets of tin-foil and paraffined paper, and possesses a capacity of $\frac{1}{30}$ to $\frac{1}{40}$ microfarad. A condenser, whilst stopping the passage of direct currents, permits alternating currents to pass through, although somewhat impaired in strength. Owing to this property, a pair of field telephones, with their condensers in circuit, may be attached to an existing telegraph line, and messages sent without interference. The direct currents used in telegraphy cannot pass through the telephones owing to the condenser; and the alternating currents due to the telephones do not affect the telegraph instruments; and hence both operations may proceed simultaneously. This fact is frequently taken advantage of in the field. It is also customary to use a condenser in the circuit when tapping a telephone line, as less current is then diverted through the instrument used for tapping, and the communication from end to end not unduly interfered with. In the D Mark II telephone a condenser is permanently in the circuit; in more modern forms, such as the D Mark III, Stevens' and Siemens' instruments, the use of the condenser is optional, and is only resorted to for the special purposes mentioned above.

7.—*Earth Contacts.*

The use of an earth return for field telephone has the advantage of saving a second line, with the attendant trouble of laying out. Contact with the ground is secured by means of a pointed iron pin, about 14 in. long and $\frac{3}{4}$ in. in diameter, which is driven in to a

depth of several inches. This pin carries a terminal, and is connected to the telephone by a short wire. In damp ground a pocket-knife, or even a wire inserted into the ground, gives sufficient contact. In dry, sandy ground it is difficult to secure a good "earth," and it is necessary to pour water round the pin. Should this fail, a return wire must be used.

In the D Mark III and Siemens' telephones a metal base, permanently connected to the earth terminal, is provided, so that when placed on the ground an earth-pin is unnecessary. The International Electric Co. provide a special heel-plate, to which a wire from the telephone may be attached, so that a telephonist may use his instrument whilst walking.

the side; and a soft portion of the leather lid enables the buzzer to be worked without opening the case. A shoulder-strap is provided, and the total weight is about 5½ lb. The circuit is identical with Fig. 1, with the addition of a condenser between the armature D and the screw A.

The chief defects of the instrument are the unsuitable character of the buzzer for Morse signalling; the high current required to work the buzzer, which soon exhausts the cells; and the liability of the connecting cords of the microphone and receiver to breakage. It requires constant supervision to keep in order, and its complete withdrawal in favour of the D Mark III will be an unmixed advantage.

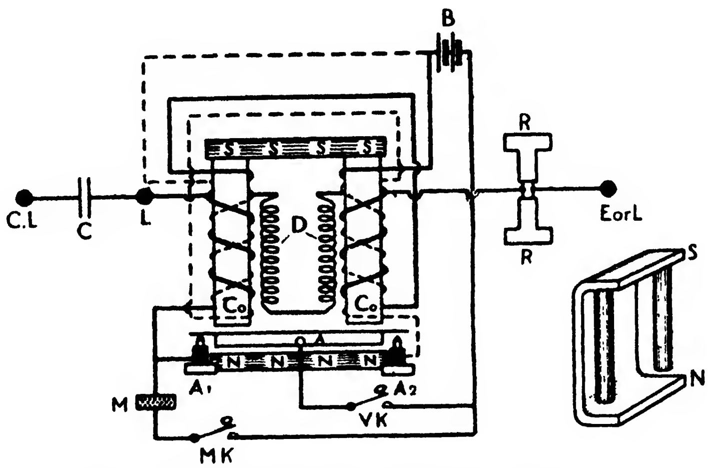

FIG. 3.—CIRCUIT OF D MARK III FIELD TELEPHONE.

DESCRIPTION OF FIELD TELEPHONES.

1.—*The Service D Mark II.*

This pattern was much used at the commencement of the war. It superseded an older and smaller form known as the Mark I, but is in turn being rapidly replaced by the Mark III. It possesses a simple buzzer, mounted with the induction coil on a fibre block. Beneath this are placed two dry cells, and a metal box containing two condensers, one of which is connected permanently to the line circuit, and the other placed across the buzzer terminals to diminish sparking at the contact with the armature. The microphone and receiver are connected by flexible copper wires to terminals on the top of the fibre block; and the whole is contained in a leather case provided with pockets for holding the microphone and receiver when not in use. The line and earth terminals protrude from

2.—*The Service D Mark III Telephone.*

The special features of this instrument, which is the latest Service pattern, are the use of a polarised buzzer; and the arrangement by which the windings round the cores of the buzzer are made to constitute the induction coil. The circuit is shown in Fig. 3, and at first sight appears complicated. The action of the buzzer resembles that of the polarised bell used in ordinary telephones, but whereas this bell is actuated by an alternating current, a direct current only is available for the buzzer. The same result is secured, however, by causing the battery current to pass alternately through each of two windings round the cores, which, being oppositely disposed, produce opposite magnetic effects. The iron cores, Co, are mounted on the south pole, S, of a permanent magnet bent twice at right angles, as shown at the side of Fig. 3. The lower extremities

of the cores will therefore possess S polarity. An iron armature pivoted at its centre is placed between the ends of the cores and the N pole of the permanent magnet. The upper face of this armature has N polarity, and carries at either extremity a thin strip of steel. In the position of rest, one of these strips touches an adjusting-screw A_1, the other being free of the screw A_2. Each core possesses two windings, one right-handed and the other left. On pressing the buzzer key, V.K, the current flows through the armature to the screw A_1, and thence round the cores by the path indicated by the full line. This results in the S pole of the core opposite A_1 becoming strengthened, whilst that of the core opposite A_2 is weakened; and hence the armature is drawn away from A_1 and makes contact at the other end with A_2. The circuit completed by this contact is shown by the dotted line, and the effect now is to strengthen the S pole opposite A_2 and to weaken the other. Hence the armature leaves A_2 and again makes contact with A_1, and thus is set into rapid vibration. When the screws are properly adjusted, so as to make the throw of the armature even on both sides, a keen, sharply-defined note is obtained, suited in every respect to calling-up or rapid Morse signalling. This buzzer requires a minimum current of 0·1 ampere for satisfactory working, this being only about one-half that needed for a single buzzer. A better result is thus secured with less current and consequent extension of the life of the battery.

The secondary of the induction coil, D, shown in the drawing at the sides of the cores, is wound over the buzzer coils, and every make or break of contact between the armature and the screws results in the production of an induced current in the secondary circuit, which, passing through the line and receivers at both ends, produces a response to the note of the buzzer.

The microphone, M, is connected so that when its key, M.K, is pressed the current passes through the full line winding of the buzzer cores, which then serves as the primary of the induction coil, the fluctuations in current caused by speaking into the microphone resulting in induced currents through the secondary circuit as in the case of the buzzer.

Two receivers, R, are used, joined to the same terminals. The terminal marked L or E is connected to a metal plate at the base of the instrument, which serves as earth contact. The condenser, C, is placed between the terminals L and C.L, and is only in the circuit when the line is connected to the latter.

The appearance of the instrument is shown in Fig. 4. It consists of two compartments, provided with lids, the taller containing the cells and the lower the buzzer and condenser. On the lower lid are mounted the buzzer key, terminals for the two receivers and microphone, marked R and M respectively; and also three terminals lettered L, C.L, and L or E, for connection to line and earth. The buzzer itself is fastened on the under side of the lid, and the condenser is at the bottom of the compartment.

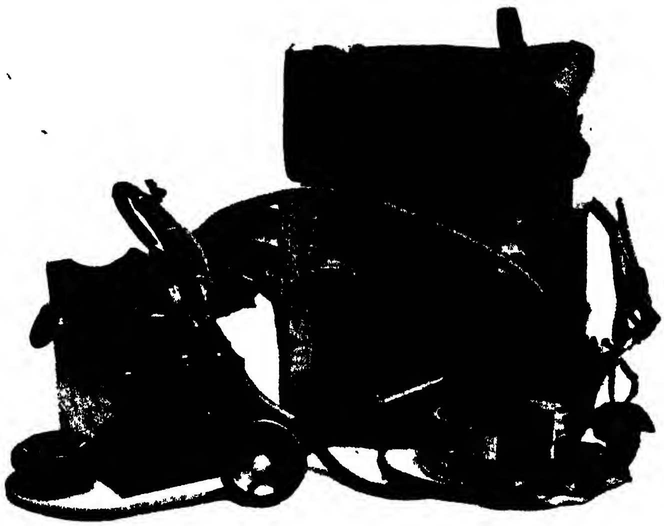

FIG. 4.—D MARK III TELEPH

One of the two receivers is contained in a leather case provided with a head-strap, so that it may be fastened to the ear when awaiting a call, leaving both hands free. The other receiver forms the upper part of a hand combination, which may be telescoped into a small size for packing; the lower part being the microphone, the key of which is in the handle. For transit, all the parts are placed in a leather case, 8½ in. × 4 in. in plan, and 6½ in. high, to which a shoulder-strap is attached. The total weight is a little over 8 lb.

The use of two receivers is a distinct advantage. If the cords of one should break the other may still be used, and the line circuit remains intact. A very important message may be heard simultaneously by two men, the risk of misinterpretation being thereby greatly reduced. Further, one of the receivers may be detached and re-wired if necessary, without putting the telephone out of action. The clear note of the buzzer is of great value, as Morse code messages are frequently the only means of communication in the firing line, talking being inaudible. The only weak point is the tendency of the connecting cords to break, and this might be overcome by the use of stranded steel wire instead of copper. With this improvement, and renewal of the cells when the voltage of each falls below 1·3, this telephone would remain in order under all normal conditions.

3.—*Siemens' Field Telephone.*

This instrument, shown in Fig. 5, resembles the D Mark III in the respect that a polarised

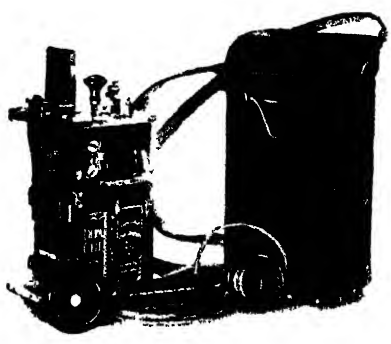

FIG. 5.—SIEMENS' FIELD TELEPHONE.

buzzer is used. A separate induction coil is employed, however; and a single receiver is provided, forming part of a hand combination. Two dry cells are used; and the various parts and terminals are fastened to a wooden frame, which, together with the hand combination, fits into a leather case provided with a sling. This case has a metal base, connected to the earth terminal, so that when placed on the ground and coupled to line, the telephone is ready for work. For all practical purposes it may be regarded as equivalent to the Mark III, except for the absence of the second receiver and head-strap.

4.—*Stevens' Field Telephone.*

Amongst the telephones used to augment the Service pattern, the form devised by Stevens (Patent 23172, 1911)* has been much used. It is illustrated in Fig. 6 (p. 888), and possesses several distinctive features. A simple buzzer, operated by the primary of the induction coil, is used, and a second adjusting screw, external to the circuit, is provided for the purpose of regulating the throw of the armature and producing a keener note. Four dry cells are provided, only two of which are normally used; but when the note of the buzzer weakens, the other two may be brought into the circuit by turning a knob. The use of the condenser is optional, three terminals, lettered as in the D Mark III being provided. The receiver and microphone are separate, each being of watch form, and strongly constructed. The outfit is packed in a leather case with sling, the total weight being 6¼ lb.

The note emitted by the buzzer is loud and has a high pitch, so that it could be heard above the noise of gunfire, but is not so sharp as that produced by a polarised buzzer. The reserve of cells is a distinct advantage, as in many situations it is difficult to procure a new supply.

Upkeep of Field Telephones.

In order to keep a telephone in working order, the operator must thoroughly understand his instrument, and be able to test each part and perform the necessary adjustments. In order to discover the condition of the various parts, the following tests are conducted in the order given:—

Test 1.—Press the buzzer key, adjusting the screws if necessary. A loud buzz should be obtained; if weak, it denotes that the cells have run down and should be renewed; this may be confirmed by a pocket voltmeter. If no buzz can be produced, a connection is probably loose, and the circuit must be examined; or possibly the cells are badly run down or short-circuited.

* Made by the International Electric Company, Ltd. Kilburn, N.W.

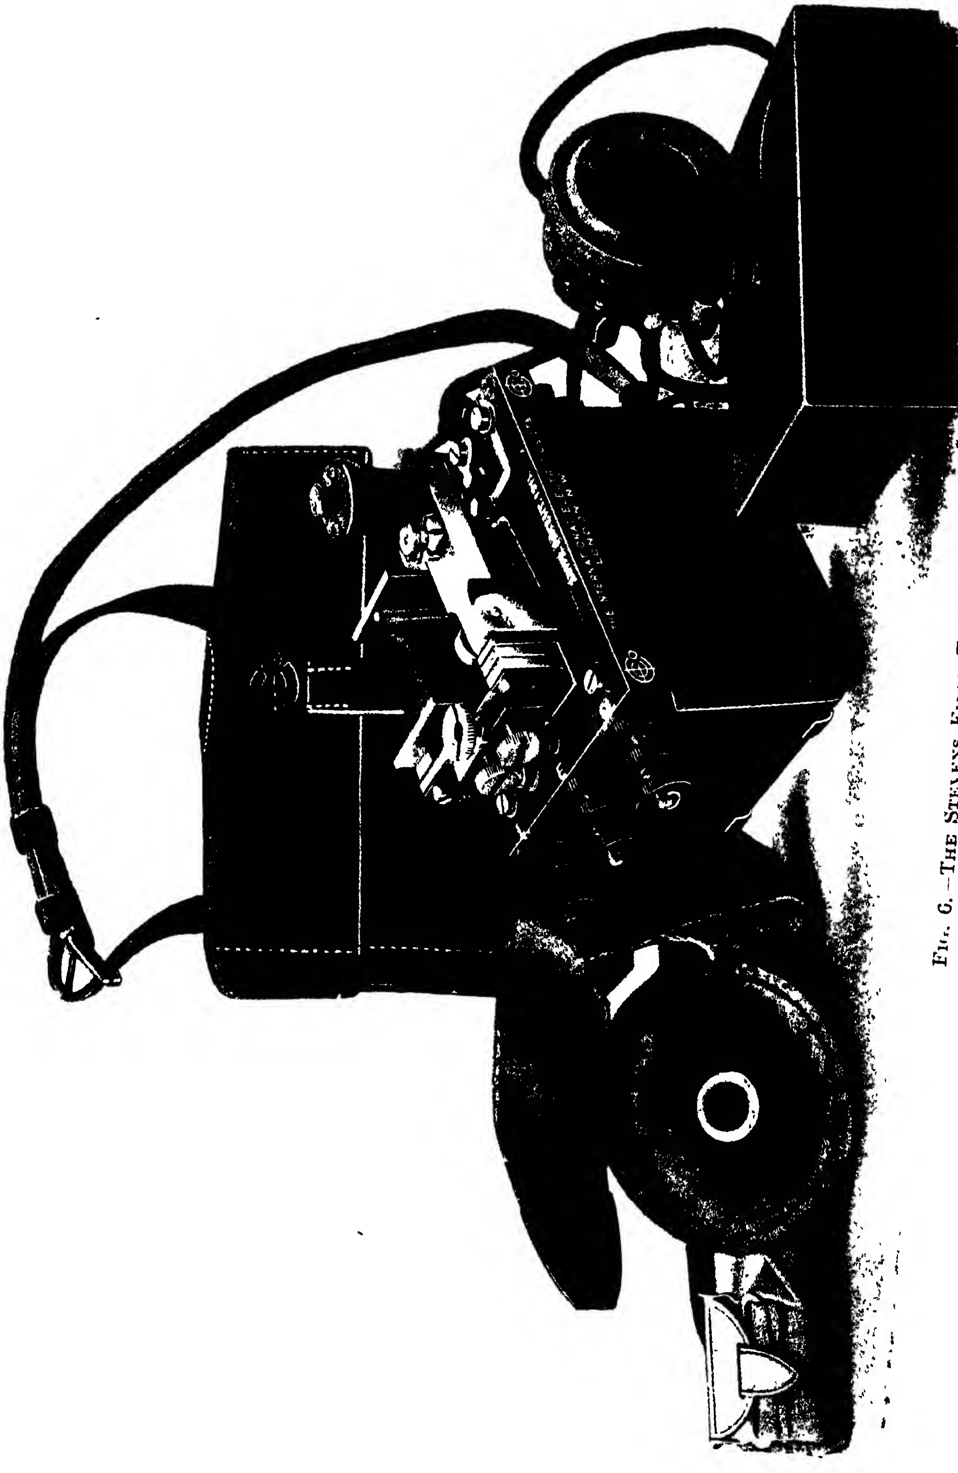

FIG. 6.—THE STEVENS FIELD TELEPHONE.

Test 2.—Connect the line and earth terminals by a short piece of wire, and press the buzzer key. It should sound loudly in the receiver. If not, the receiver cords are broken or loose, or the receiver is short-circuited. More unlikely causes are the diaphragm touching the poles of the magnet, or a break in the windings of the coil. The defect, whatever it may be caused by, must be remedied at once.

Test 3.—Without removing the wire connecting L and E, press down the microphone key. A click should be heard in the receiver, both on contact and release of the key. On blowing into the microphone, the sound should be heard in the receiver. If no sound is heard, either the cords are loose or broken, or the microphone is short-circuited, or the capsule is damaged and requires renewal.

Any telephone responding successfully to these three tests may be regarded as in good condition; and if afterwards a message cannot be transmitted, the fault lies in the line or in the telephone at the other end. Unless the telephone be in working order, as indicated by the tests, any attempt to use it would be futile.

The Laying and Upkeep of Lines.

The lines for field telephones are made of steel wire, which possesses greater mechanical strength than copper wire, and is therefore not so easily broken. A thin, single-stranded steel wire, with an insulation of varnish, is much used when a temporary communication has to be established, or when a body of men moving forward have to keep in touch with the rear. Such a wire has the advantage of lightness, and a considerable length may be contained on a small reel. For work of a more permanent character, wires composed of several steel strands, and insulated with rubber and woven fabric, are used, and are less liable to short circuits to earth than the former. Reels of different sizes, according to the length of wire contained, are employed; the smaller reels are carried on a body-belt by the linesman, whilst the larger are mounted on special barrows. The lines are laid on the surface, or placed a few inches underground, according to circumstances, and in the latter case perfect insulation is absolutely necessary. In laying a surface wire between two stations, the safest route, even if circuitous, is taken. Open spaces are avoided, the wire being laid along a hedgerow in preference to crossing a field. If a road has to be crossed, two trees or other suitable objects are chosen, the line being tied to the base of the first tree and drawn tightly up the trunk, and then passed over a suitable fork at a minimum height of 15 ft. It is then passed over a fork on the opposite tree, drawn tight across the road and down the trunk, and secured at the base. In the absence of trees or poles the line must be buried in the road. A line should, if possible, be kept at least ten yards away from any other line, otherwise induction effects will give rise to overhearing in both, and cause confusion.

The breaking of telephone lines by fragments of bursting shells is a very common occurrence, and as the cutting-off of communications may have very serious results, measures are taken to maintain a complete circuit as long as possible. To this end multiple lines are used, and one arrangement, known as the "ladder" system, is indicated in Fig. 7. The wire is formed into

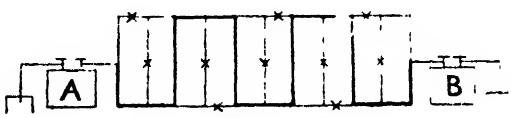

FIG. 7.—THE "LADDER" SYSTEM OF TELEPHONE LINES.

a network resembling a ladder, with a connection at either end to the telephones A and B. Although numerous breaks may occur, as indicated by the crosses, a continuous circuit from A to B, marked out by the thick line, still exists. Networks of this kind are sometimes buried in the ground, and enable communication to be kept up for long periods. The method has two drawbacks; first, a large number of joints have to be made during laying; and, second, each break is liable to cause a short circuit to earth, difficult to locate, which would prevent messages passing between the two ends.

An alternative method is shown in Fig. 8, where four lines are laid between the telephones A and B, which at one spot are brought to junctions D in a dug-out, where a linesman is placed provided with a telephone. C. It must be understood that the lines, shown parallel in the drawing, may take widely different routes between the ends and the dug-out. As indicated by the crosses, all the lines are broken; 1 and 4 on the right, and 2 and 3 on the left of D. By joining each line in turn to the telephone C, these breaks and their bearings may be discovered; thus, by connecting to 4 it will be found possible to communicate with A, but

not with B, and hence a break on this line between D and B is inferred. Similarly it would be found that 2 is whole between D and B, but broken on the other side. By joining the whole portions of the lines 4 and 2, or 1 and 3, at the junction-box D, a continuous line between A and B is again established. Knowing the direction of the breaks, the linesman takes a favourable opportunity of repairing them, the repair being executed by laying bare the wires at the broken ends and tying them together by a reef knot, the bare part being then insulated with rubber tape or tubing. This method has the advantage that a break may be located, and that a broken line which causes a short circuit to earth may be disconnected until the broken part has been repaired.

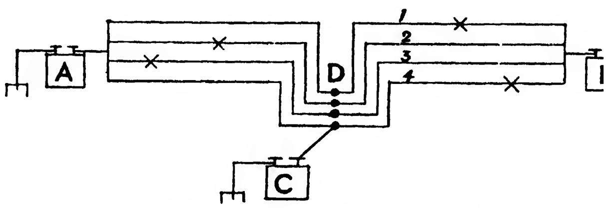

FIG. 8.—MULTIPLE LINE SYSTEM.

FIELD EXCHANGES.

When several telephones require to be kept in touch, an exchange is used. A battery commander may thus communicate with his observer, ammunition waggons, and guns, or any of these units with each other. A small portable exchange, provided with plugs or switches, is used in this and similar cases.

DUTIES OF A FIELD TELEPHONIST.

The office of field telephonist is one of great responsibility. He must be capable of keeping his instruments in order, and of executing ordinary repairs such as re-wiring the parts. He must also be capable of laying lines, detecting and locating breakages, and repairing them satisfactorily. He must also be able to transmit and receive messages by Morse code at a minimum rate of twelve words per minute. He is often compelled to act in an emergency, frequently at risk of his life, in order to restore or keep up communication. His everyday duties demand knowledge, skill, and courage, and are important in the highest degree.

CONCLUSION.

The subject of field telephones is a wide one, and it has only been possible in this lecture to touch on its main features. It will have been gathered, however, that the training of a field telephonist cannot be accomplished by drill alone. He must, if he is to be thoroughly reliable, possess a knowledge of the working parts of his instrument, so as rapidly to detect and rectify a fault. And this leads me to suggest that science teachers throughout the country might with advantage be used to impart this necessary knowledge in all localities where special instruction is not available. Such instruction should be carried out on an approved plan, and would require co-operation with the military authorities, in order that the actual instruments might be available for demonstration. By this means an abundance of reliable men could be secured in a short time, and with little expense. There has been much nebulous talk about the "mobilisation of science," but to obtain efficient results it is necessary to provide each man with work suited to his experience and qualifications. This condition would be fulfilled by utilising capable teachers for the training of field telephonists, and the results would, in my opinion, be of great value to the country at the present juncture. A properly organised scheme would not be difficult to produce, would cost little in operation, and would enable the country to take advantage of the special qualifications of teachers of science.

STANDARDISATION OF BOMB CALORIMETERS.

There has recently been issued by the United States Bureau of Standards a paper describing briefly the methods of calibrating and using bomb calorimeters, such as are used in determining the amount of heat available from a given weight of coal or coke or other combustible. The amount of heat which can be obtained depends largely upon the kind and quality of fuel. When purchased in large quantities, therefore, a fuel is commonly tested to determine the amount of heat available per pound, and the price paid depends upon the results of these tests.

The instrument used for such tests is called the bomb calorimeter, and consists essentially of a steel shell or "bomb" in which a small weighed

sample of the fuel can be burned in pure oxygen gas. The bomb is immersed in a known amount of water before the sample is ignited, the heat produced warms the water, and by suitable measurements of the change of temperature the amount of heat can be calculated.

Provision is made by the Bureau of Standards for standardising bomb calorimeters by means of standard samples of certain pure materials, viz., sugar, naphthalene, and benzoic acid. By burning known amounts of these substances in the bomb the observer determines the amount of heat required to raise the temperature of the bomb and water 1°. This being determined, the amount of heat furnished by a given sample of coal burned in the same bomb with the same amount of water can be found.

Thus these standard samples, which are sent all over the United States, serve as standards of heat and make it possible to get the same results from tests made anywhere, much as the use of the standards of length and of mass makes a yard or a pound the same everywhere.

MANJACK DEPOSITS IN THE BRITISH WEST INDIES.

Trinidad.

There are in the island of Trinidad large deposits of manjack, especially in the San Fernando section, where are situated the Vistabella and the Marabella properties. During the past decade approximately 18,000 tons were exported in a crude state.

In outward form and general appearance manjack is not unlike fine coal, and is essentially a bituminous substance. It is an oil residuum occurring in lenticular seams between walls of peculiar clay, which appear to have absorbed the oil under very heavy pressure. It is jet black in colour and resinous in its nature, and has long been known for its insulating properties in the manufacture of electric coils, dynamos, and generators.

From a recent report by the United States Consul in Trinidad, it appears that the Vistabella manjack properties are worked under a long lease by an American company, which, besides exploiting and exporting manjack in its natural state, has undertaken the manufacture of certain well-defined compounds. One of these is a high-grade black manjack paint for use on smokestacks and on boilers, both inside and out; another is a preparation suitable for greasing pipe threads, dressing wire rope, etc.

Barbados.

Barbados manjack is of two varieties—the conchoidal and the columnar. The first is the more valuable, and a newly-fractured specimen cannot be distinguished from jet, so far as outward appearance is concerned. At the present time the exportations are mainly to the United States, where Barbados manjack is used in the manufacture of high-grade insulating black varnish.

AGRICULTURE IN THE FEDERATED MALAY STATES.

It appears from the Selangor Administration Report for 1914 that the approximate areas under different kinds of cultivation in that State last year were as follows:—

	Acres
Rubber	245,503
Coconuts	35,092
Coffee	9,953
Padi	9,448
Various	22,000

Rubber shows a substantial increase over the previous year's figures, but there is a decrease under the head of coconuts. The latter is inexplicable, as the cultivation of coconuts is steadily extending. The area under padi has increased by nearly 3,000 acres, and the development of this form of cultivation is most satisfactory.

As regards Negri Sembilang, the State Administration Report for 1914 gives the following figures as showing approximately the areas devoted to the principal products cultivated in that State last year:—

	Acres
Rubber	117,000
Padi	28,000
Coconuts	20,000
Gambier	4,500
Tapioca	1,300
Fruit trees	12,000

About 3,300 acres are under various other products.

CORRESPONDENCE.

DESTRUCTION OF WASPS.

I have recently discovered (and I do not know if the fact is generally known) that the vapour of benzol and petrol is quickly fatal to wasps and many other insects. Touched with a brush dipped in either spirit they instantly collapse and die.

During the past few days I have destroyed three wasps' nests by the injection of about 2 oz. of benzol into the nest by means of a small syringe. The first injection is sprayed over the mouth of the nest. This entirely prevents the escape of any of the insects, and kills the sentry wasps at once The balance is sprayed right into the hole.

One partly destroyed nest was laid open, and several hundred wasps were found, covering an area as large as a cheese plate. The first discharge of the syringe over these killed the lot, and not one escaped. The gas is not ignited in any way, but acts probably either by asphyxiation or by producing a fatal anæsthetic effect.

The method is so simple and easy of manipulation, that I feel it cannot be too widely known, and as it involves the use of no dangerous or poisonous substance, is highly to be recommended where these pests abound.

A. H. Mitchell.

Horn's Green,
Knockholt, Kent.

GENERAL NOTES.

NUMBER OF THRASHING MACHINES IN ITALY.—According to a census lately made by order of the Minister of Agriculture in Italy, it seems that the total number of thrashing machines in that country does not exceed 11,000. Of this number 2,800 are to be found in the region of Emilia. The shortage of labour in the rural districts in consequence of the present war conditions is causing considerable uneasiness amongst the landowners and farmers generally. The Government are taking steps to utilise all existing harvesting and thrashing machinery to the best advantage during the coming harvest. Last spring forty haymaking machines were placed at the disposal of the agricultural societies by the Italian Government, in order to facilitate the rapid storage of forage.

WHEAT IN EGYPT.—According to a note in the *Bulletin* of the Imperial Institute, wheat in Egypt in an ordinary year occupies about 17 per cent. of the total cultivated area, only maize (24 per cent.) and cotton (23·3 per cent.) occupying a larger total. In spite of this the export of wheat is small, and more than counterbalanced by the amount imported. Thus in 1913 about 2,400 tons were exported, mainly to Turkey, and 4,600 tons were imported, chiefly from India. In addition to this, large quantities of wheat-flour were imported. In September, 1914, on account of the anticipated reduction in the demand for cotton in the world's market, a decree was promulgated in Egypt that not more than 1,000,000 acres, or three-quarters of the area put down to the crop in 1914 were to be planted with cotton. The land thus set free was to be devoted to cereals, in the hope of rendering the country more independent of outside supplies, and of probably producing a surplus for export. Wheat is, of course, a winter crop in Egypt, and is grown in about equal amounts in Upper and Lower Egypt.

CONDITION OF RUSSIAN LINEN INDUSTRY.—Since the beginning of last autumn the Russian concerns engaged in the manufacture of linen have been extremely busy meeting the large demand for coarse flax fabrics, tarpaulin, sacks, etc. The spinning mills have also increased their production in consequence of the extensive demand on the part of the weavers and other buyers of flax thread. The prices of both flax yarn and manufactured goods have increased. Last year one hundred bags were valued at £3 to £3 4*s.*, according to their weight, while now prices have reached £4 1*s.* 6*d.* to £4 6*s.* Average grades of yarn have risen in price from £1 2*s.* 6*d.* to £2 7*s.* 10*d.* for No. 14, and from £1 14*s.* to £2 3*s.* for No. 30. At the same time the manufacturing concerns have been deprived of a great number of experienced workmen, and are now suffering from the lack of hands. Many weaving mills have introduced a system of working in two shifts of nine hours each. In some kinds of work the men have been replaced by women and minors with considerable success. There is, however, a great lack of combers, as this kind of work has proved beyond the physical power of women. The price of labour has increased, daily wages having risen by 2½*d.* to 5*d.*, and monthly pay by 6*s.* 5*d.* to 10*s.* 9*d.* From a recent report by the United States Consul-General at Moscow, it appears that a considerable proportion of the weaving is done in the cottages of the peasants having their own looms, and receiving the yarn from the contractors. One weaver can turn out two, three, and four pieces of linen per week. The price of labour per piece is now 2*s.* 11*d.* to 3*s.*, against 1*s.* 6*d.* to 1*s.* 8½*d.* paid previously. According to official data, there are twelve flax spinning mills in the Province of Vladimir (the principal district of the flax industry), while there are 110 weaving mills with 21,659 workmen. In 1908 there were ten spinning mills and only twenty weaving mills.

COAL DEPOSITS IN SWEDEN.—Dr. Edward Erdmann, State Geologist of Sweden, has made investigations regarding the coal area in the Province of Scania, and according to his report, quoted by the United States Consul at Goteborg, the coal deposits there are calculated to amount to 106,500,000 tons. The rate of mining during the last few years has been only about 300,000 tons per annum. The annual consumption of coal in Sweden amounts to about 4,500,000 tons, and the domestic production supplies only about 7 per cent. of this, while the balance, or 93 per cent., must be imported from abroad.

JAPAN'S PAPER TRADE.—In a report to the U.S. Department of Commerce by Consul-General George H. Scidmore, Yokohama, Japan, it is stated that since the war interfered with the European paper trade inquiries have come to Japan from all over the East for paper, especially for news-print paper. The first export orders were from Hong-Kong, followed by Tientsin, Shanghai, and the Yangtze ports. More recently orders have been received from Bombay, Calcutta, and Manila. About 1,000,000 lb. is the present monthly export, and according to the *Mainichi* (Osaka), Siberia and Australia are the only markets in these longitudes not taking Japanese paper. Tientsin is the largest consumer, taking about half the China imports. Inquiries are being received from China for qualities of paper other than news-print paper, but the news trade is believed to be the most promising one, and as the foreign demand increases more rapidly than the Japanese, the *Japan Chronicle* believes that Japan will be quite capable of capturing the whole of the Oriental trade, and even of holding on to it in the face of the restoration of competition which will be seen when the war ends. Although Japanese news-print is confessedly poor stuff, it is hoped to hold the market by the low price.

NOTICE.

INDIAN SECTION COMMITTEE.

The following is the list of the Indian Section Committee, as appointed by the Council: -

Dugald Clerk, D.Sc., F.R.S. (Chairman of the Council)
Sir Steyning William Edgerley, K.C.V.O., C.I.E. (Chairman of the Committee).
Lord Ampthill, G.C.S.I., G.C.I.E.
Sir Arundel T. Arundel, K.C.S.I.
Sir J. Athelstane Baines, C.S.I.
Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I.
Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Lieutenant-Colonel Sir Charles Henry Bedford, LL.D., D.Sc., M.D., I.M.S. (retd.)
Thomas Jewell Bennett, C.I.E.
Sir M. M. Bhownaggree, K.C.I.E.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Sir Valentine Chirol.
William Coldstream, B.A., I.C.S. (retd.).
Laurence Currie, M.A., J.P.
Right Hon. Earl Curzon of Kedleston, G.C.S.I., D.C.L.
Sir William Duke, K.C.S.I., K.C.I.E.
Right Hon. Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E.
James Fairbairn Finlay, C.S.I., I.C.S. (retd.).
Sir Frederic W. R. Fryer, K.C.S.I.
Sir Krishna Govinda Gupta, K.C.S.I.
Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Sir Philip Perceval Hutchins, K.C.S.I.
Lord Inchcape, G.C.M.G., K.C.S.I., K.C.I.E.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

FOODSTUFFS.

By David Sommerville, B.A., M.Sc., M.D.,
Assistant Professor of Hygiene and Public Health, King's College, London.

Lecture I.—Delivered April 26th, 1915.

When it is considered that the growth, development and power to function of all the tissues of the body are derived directly from the foods taken into the alimentary canal, there need be no apology for investing these substances with an importance of the first order.

This discussion will be concerned only with certain aspects of the subject which at the moment appear to be of special interest.

Upon many workers in the field of practical medicine the conviction has of late been forced that largely, if not wholly, in proportion as we understand aright what happens to foods as they enter the body, are incorporated with the cells of the organism, and as so much waste material finally leave it, so can we hope to be able to assist the body in disease, and that in this matter all other considerations are of but minor importance.

It has been customary to classify foodstuffs in four categories: (1) Proteins; (2) Carbohydrates; (3) Fats; and (4) Inorganic Substances. Of these the proteins are by far the most complex.

In the forties of last century Mulder wrote of "protein" as a single body, "forming different compounds with phosphorus and sulphur, and presenting accordingly differences in appearance and physical properties." This author tells us that "it has received the name 'protein' because it is the origin of so many dissimilar bodies and is itself a primary substance." Liebig's notions of protein were somewhat similar. We now know that there are some forty to fifty proteins occurring in animals and

plants, and that chemically their structure is the same in the two kingdoms. In 1728 Beccari informed the Academy of Bologna that in wheat flour he had found two types of substance - "those things which are extracted from vegetables, and another which it appeared impossible to extract except from animal matter." After this discovery the presence of coagulable protein was soon recognised in the juices of different plants: and the similarity of this substance to egg albumin caused it to be known for a long time as albumin.

Various methods have been employed for determining the composition of the protein molecule. Of these hydrolysis by acids, hydrolysis by alkalies, and hydrolysis by proteoclastic enzymes have proved the most fruitful.

The sharp line of demarcation which formerly was drawn between proteins on the one hand as nitrogen-containing bodies, and carbohydrates and fats on the other as non-nitrogenous bodies, was modified considerably when it became known that the protein molecule contains one or more carbohydrate groups. The study of the production of sugar from protein in diabetes has enlarged our conceptions of the nature of the protein molecule. The work of Schutzenberger, Horbaczewski, Schulze, and others on the products of hydrolysis of proteins, resulted in the separation of a number of amino-acids. Investigations on the chemical constitution of these had been going on for several decades when Emil Fischer, about the beginning of the present century, took up the work, and by the introduction of his new ester method of separating mono-amino-acids from protein digests, threw a flood of light on the characters of a number of these bodies. It is now fairly clear that the protein molecule is mainly constructed of a series of amino-acids. The following have been separated: –

$CH_2 . NH_2 . COOH$, amino-acetic acid or glycine.

$CH_3 . CH(NH_2) . COOH$, a-amino-propionic acid or alanine.

$CH_3 . CH_2 . CH(NH_2) . COOH$, a-amino-butyric acid in casein.

$(CH_3)_2CH . CH(NH_2) . COOH$, a-amino-isovalerianic acid or valine.

$(CH_3)_2CH . CH_2 . CH(NH_2) . COOH$, a-amino-isocaproic acid or leucine.

An isomeride of leucine, a-amino-n-hexoic acid (separated by Abderhalden and Weil from nervous tissue).

Isoleucine, $\frac{CH_3}{C_2H_5}CH . CH(NH_2) . COOH$.

$C_6H_5 . CH_2 . CH(NH_2) . COOH$, β-phenyl-a-amino-propionic acid or phenyl alanine.

$CH_2 . CH(NH_2) . COOH$, β-parahydroxy phenyl-a-amino-propionic acid or tyrosine.

OH

$CH_2OH . CH(NH_2) . COOH$, β-hydroxy a-amino-propionic acid or serine.

$S . CH_2 . CH(NH_2) . COOH$

|

$S . CH_2 . CH(NH_2) . COOH$, dicysteine or cystine.

$CH_2 . COOH$

|

$CH(NH_2) . COOH$, a-amino-succinic acid or a-aspartic acid.

[$CH_2 . COOH$

|

$CH(NH_2)_2 . CONH_2$, the amide of a-aspartic acid, has been shown by Schulze to play an important part in the germination of seeds.]

$CH_2 . CH_2 . COOH$

|

$CH(NH_2) . COOH$, a-amino-glutaric acid or glutamic acid.

$\diagup NH_2$

$C = NH$

$\diagdown NH . CH_2 . CH_2 . CH_2 . CH(NH_2) . COOH$, δ-guanidine-a-amino-valerianic acid or arginine; this body, as also creatine, contains the guanidine or imido-urea group

NH_2

$C = NH$.

NH_2.

$CH_2(NH_2) . CH_2 . CH_2 . CH_2 . CH(NH_2) . COOH$, diamino-caproic acid or lysine. Another diamino compound separated from casein by Fischer and Abderhalden (constitution not at the time determined) was named diaminotrihydroxydodecoic acid.

CH — NH

$\diagdown$ CH, a-amino-β-imidazol-propionic

C ——— N

|

$CH_2 . CH(NH_2) . COOH$

acid or histidine, a heterocyclic body separated by Kossel and studied by Pauly.

CH_2 — CH_2

| |

CH_2 CH . COOH, a-pyrrolidine-carboxylic acid or proline,

NH

and CH_2 —— CH_2

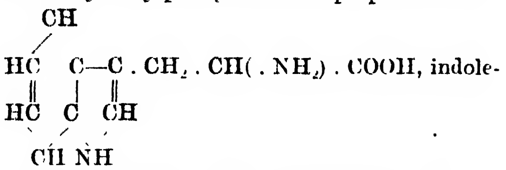
| |

CH . OH CH . COOH, hydroxy-a-pyrrolidine-

NH

carboxylic acid, heterocyclic compounds discovered by Fischer in 1901.

Guggenheim has separated from Vicia faba 3 : 4-dihydroxy-phenyl α-amino-propionic acid.



indole-α-amino-propionic acid or tryptophane, another heterocyclic compound discovered by Hopkins and Cole. Ellinger and Flamand synthesised this body in 1907.

Braconnot obtained glycine as a cleavage product of proteins in 1820, and Wohler showed afterwards that it unites with benzoic acid to form hippuric acid:

$$C_6H_5.CO.OH + H\ NH.CH_2.COOH$$
$$H_2O + C_6H_5CO.NH.CH_2.COOH.$$

Nencki considers the formation of urea as analogous to this synthesis.

Glycine contains an asymmetric carbon atom (attached to NH_2), and is accordingly optically active.

It further unites with cholic acid to form glycocholic acid of bile. By fusing glycine with urea at 230° Horbaczewski produced uric acid after Strecker had shown that heating uric acid with HCl in a sealed tube to 170° gave rise to glycine, CO_2 and NH_3. Wiener showed that glycine is produced from uric acid when administered to a rabbit.

The biochemical history of leucine, tyrosine, glutamic acid, histidine, arginine, and lysine—indeed, of all the above bodies—is teeming with interest, but obviously outside the scope of these brief observations.

It is clear that the organism must receive in its food all the elements of which its tissues are composed. This fact suggests such questions as: What becomes of a compound after it is introduced into the body; in what manner is it broken down; in what form is it finally excreted—in a word, what are the chemistry and physics of cell metabolism? Of the nature of the substances entering the body we know a little; of the nature of the substances leaving the body as excretions we know also a little; but of many of the intermediate transformations we know nothing; and of the ultimate cause of metabolism we cannot even guess. This unknown land, however, holds the richest rewards for those who can enter in and take possession.

When a protein, such as egg-white, gluten of wheat, etc., is acted on by an appropriate enzyme in the presence of water, the large complex molecule breaks down into smaller molecules. Under optimum conditions this cleavage goes on until crystalline amino- acids are formed. *In vitro* this cleavage requires the application of much more energy and a longer period of time than in the alimentary canal. In the latter, cleavage does not commence until the protein has reached the stomach, where it is subjected to the action of hydrochloric acid and pepsin. The view is generally accepted that in healthy conditions of the stomach proteins pass through the hydrolytic stage of proteoses to that of peptones, and only so far. It has been demonstrated that if gastric digestion be allowed to proceed long enough, bodies of the nature of amino- acids (abiuret products, that is, bodies which no longer give the biuret reaction) are formed. This stage of digestion need not be considered, as even under the most favourable conditions *in vitro* it requires many weeks for completion. Zuntz states that three-fifths of the products of protein digestion in the stomach enter the duodenum as peptones and two-fifths as proteoses. He shows that the condition in which the food is eaten influences the degree of digestion. Thus when a dog is fed with cooked beef there is more proteose present than when the beef is ingested raw. Further, he finds that when the pancreas is thrown out of action digestion in the stomach is more complete—that the stomach is capable of taking on an increased compensatory digestion.

Fischer and Abderhalden have shown that gastric digestion is to be regarded as preliminary to pancreatic (tryptic) digestion, since the latter takes place much more quickly and completely when the protein has been previously subjected to the action of pepsin and hydrochloric acid. They find, in the case of caseinogen, that phenylalanine and proline are present in digests previously acted on by gastric juice, but if pancreatic digestion be carried out alone the stage of amino- acids is not reached. In the duodenum trypsin acts on all forms of protein passing from the stomach, and is assisted by another enzyme—erepsin—secreted by the intestinal mucosa.

Formerly it was considered that proteoses and peptones were the end-products of digestion, but it is now known that digestion proceeds to the formation of polypeptides and mono-amino- and di-amino- acids. Abderhalden and his pupils have fed animals on meat, caseinogen, gliadin, etc., and isolated and estimated by weight tyrosine, glutamic acid, and other amino-acids from the duodenal digest. This cleavage proceeds at a much greater rate in the intestine

than *in vitro*, even under the influence of the most active enzymes. It appears that in experiments *in vitro* the enzymes in time combine with the products of their own activity and so become inactivated, whereas in the intestine, as the amino- acids are continuously removed from the field of action by absorption, there is little opportunity for such combination.

For a time Hofmeister, Neumeister, and others thought that peptone on absorption was taken up by the leucocytes, or epithelial cells of the intestinal wall, reconverted into protein and conveyed to the tissues. Others denied this, affirming that no trace of peptone had ever been found in the tissues, blood or lymph, even at the height of digestion, and that when peptone is injected into the blood it is quickly removed as waste matter.

Cohnheim tried to isolate synthesised protein from the intestinal wall, and found that the peptone reaction disappeared, not because synthesis had taken place, but because further cleavage into crystalline bodies had been effected. He isolated erepsin, and proved that with the exception of caseinogen and fibrin it could not attack native proteins, but that proteoses and peptones were readily converted into their constituent amino- acids; he isolated leucine, tyrosine, lysine, histidine and arginine.

Attention had been directed to the fact that certain amino- acids, viz., asparagine, leucine and tyrosine, in the presence of carbohydrate, could be regenerated into protein in plants; Salkowski and Leube suggested that leucine and other similar compounds were in like manner synthesised into protein in animals.

After many experiments, and much discussion, the conclusion has been reached that there is no definite evidence of the existence of proteose or peptone in the blood.

In what form, then, does protein enter the organism? Two schools make reply to this question: Abderhalden and his friends hold that synthesis takes place in the intestinal wall with formation of coagulable protein, and assert that amino- acids have not in their opinion been clearly demonstrated in the blood. Another set of observers claim that absorption takes place in the form of amino- acids.

There is no direct evidence which definitely determines the form in which digested proteins enter and travel in the blood.

The digestion and absorption of protein is followed by a large and rapid rise in the output of urea in the urine, and by a marked increase in ammonia in the portal vein. Is this deaminisation intended to preserve the concentration of amino- acids at a constant level, allowing a selected portion to pass to the tissues for architectural repair? Is it that certain amino- acids, *e.g.*, glutamic acid in gliadin, are in excess and must be eliminated? Since tissue proteins differ from one another qualitatively and quantitatively, it is argued that if the material absorbed were uniform—coagulable protein—each tissue, each cell, would individually have to break down the common pabulum in order to acquire its specific needs, and, whilst this work might be conceivably possible through the action of intracellular proteolytic enzymes, still the magnitude of it would be so great and the end so purposeless as reasonably to negative the hypothesis of immediate resynthesis. What becomes of the superfluous amino- acids if the resynthesis theory be correct? Why are they not found in the blood? Further, what is the explanation of the large increase in urea and ammonia in portal blood following protein digestion?

Inability to detect amino- acids in the blood does not prove that they are not present; and it is easier to assume with Pflüger that amino-acids, or groups of amino- acids, circulate in the bloodstream at a rapid rate, and that each cell, each tissue, draws from the fluids which bathe it the individual specific groups which it requires. The small quantities of amino- acids present relative to the whole volume of blood and the rate at which they circulate, and are absorbed, may well render it difficult to detect them.

Zuntz, Muller and others have shown that in the vegetable kingdom amides are built up into protein by certain bacteria. In this way Müller produced about 10 per cent. protein and 40 per cent. peptone from asparagine.

Much work has been done with a view to determining whether amide nitrogen alone, or in association with carbohydrate, can take the place of protein nitrogen in (1) adult animals, so as to maintain nitrogen equilibrium, and (2) in growing animals so as to maintain growth. The results are conflicting. Working with adult rats, I have in no instance been able to maintain N-equilibrium by feeding asparagine and carbohydrate, and the loss in N was greater when asparagine alone was fed. In the case of young white rats, asparagine, with or without carbohydrate, not only failed to effect growth, but in every case led to rapid loss of flesh. Control animals from the same litter were used in each set of experiments, and a normal fat ration was supplied in all cases.

Voltz, some eight or nine years ago, claimed

that acetamide and ammonium acetate were capable of effecting a retention of N in dogs; and that in ruminants these bodies could replace two-thirds of the protein of the food. My experiments in feeding white rats, both adults and young animals, with acetamide and ammonium acetate have failed to confirm the findings of Voltz.

Practically all the amino-acids with which we are acquainted have been found in the digestion of proteins in the intestine of the higher animals by one or other of the many workers in this field, in small quantities in some cases it may be, but in others in quantities of considerable size. That these bodies can no longer be considered as so much waste material is now clear, inasmuch as they are known to be able to take the place of proteins as foods, and when absorbed are as completely oxidised as proteins. Further, considered as sources of energy, they are more valuable than proteins. A gramme of tyrosine has been shown to yield practically 6 calories, and a gramme of leucine 6·5 calories, as against 4·1 calories yielded by a gramme of coagulable protein. Animals have been kept in nitrogenous equilibrium for many days without the ingestion of any protein, but instead the finished products of the tryptic digestion of proteins in which no biuret reaction could be detected.

It is of interest to note that certain products of acid hydrolysis are not absorbed. Acids can carry the hydrolysis of proteins further than proteolytic enzymes; so, it is assumed that certain linkages are broken by acids which are left intact by enzymes, and that the organism is unable to couple again the severed bonds. Again, in the case of racemic amino- acids, the organism is only capable of dealing with the body which occurs in nature, the optical isomer remaining unabsorbed and appearing later in the urine.

Reference may now be made to some experimental work on the rapidity of gastric digestion in the human subject.

Hot trichloracetic acid precipitates native proteins from blood serum, filtered gastric digest, urine, etc., but not proteoses, peptones, or amino- acids. Saturated $ZnSO_4$ solution precipitates proteoses, but not peptones or amino-acids. A 7 per cent. solution of tannic acid also precipitates proteoses, but not peptones or amino- acids and in certain cases is preferable to $ZnSO_4$ solution. A solution composed by weight of 10 parts H_2SO_4, 40 parts phosphotungstic acid, and 50 parts water, precipitates proteoses, peptones, and diamino- acids, but not mono-amino- acids. The method of separating and estimating amino- acids is mostly a lengthy process, involving evaporation in vacuo at a low temperature, saturation with HCl gas, solution in alcohol, etc., and even in the cases where comparatively large quantities of particular amino- acids are present the process gives only approximately correct results. In gastric work, with but very few exceptions, no such method is needed.

Before commencing an investigation, it is well to make some preliminary estimations with definite quantities of purified products, not only to be certain of the purity and normal activities of the various reagents used, but also to test one's own ability in securing accurate results. In this work I have found that by careful scrutiny of the individual reactions results defaulting by 2 or 3 per cent. may be reduced to well within 1 per cent. of error.

The following are transcribed from my case-book :—

P = native protein, P_1 = proteose, P_2 = peptone.

1. Healthy man æt. 30 had test breakfast of caseinogen mixed with water and a small quantity of NaCl on four separate occasions. On the first occasion the entire gastric contents were drawn off at the end of one hour; on the second occasion at the end of two hours; on the third occasion at the end of three hours; and on the fourth occasion at the end of four hours. The relative percentage proportions of P, P_1, and P_2 were as follows :—

1st hour.			2nd hour.			3rd hour.			4th hour.		
P	P_1	P_2	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2
70	21	9	65	18	17	56	20	26	52	19	29

The same subject had later four test breakfasts of red meat, freed from fat and white fibrous tissue, slightly grilled, with a small quantity of NaCl and a glass of hot water.

The relative percentage proportions of P, P_1, and P_2, at the end of one, two, three and four hour periods respectively were as follows :—

1st hour.			2nd hour			3rd hour.			4th hour		
P	P_1	P_2	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2
76	14	10	70	16	14	60	19	21	54	20	26

2. Man æt. 38. Suffering from gastric catarrh. Same procedure.

	1st hour.			2nd hour			3rd hour			4th hour.		
	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2
Caseinogen	92	8	0	86	12	2	85	8	7	84	8	8
Red meat	93	7	0	88	8	4	86	7	7	85	8	7

3. Man æt. 38. More pronounced symptoms of gastric catarrh.

	1st hour.			2nd hour.			3rd hour.			4th hour.		
	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2	P	P_1	P_2
Caseinogen	88	8	4	80	12	8	70	15	15	64	16	20
Red meat	90	6	4	82	11	7	68	20	12	66	16	18

I have been sufficiently fortunate in securing the analyses of three cases of stomach contents, vomited after ingestion of a meal by patients in a condition of exhaustion following muscular activity. The stomachs were washed with warm water at the time of vomiting, and the washings added to the vomits.

Case 1, man æt. 27. Vomiting occurred $4\frac{1}{2}$ hours after a mixed meal: $P = 95$ per cent., $P_1 = 3$ per cent., $P_2 = 2$ per cent.

Case 2, man æt. 34. Vomiting occurred $3\frac{1}{4}$ hours after a mixed meal: $P = 89$ per cent., $P_1 = 5$ per cent., $P_2 = 6$ per cent.

It is clear that, in certain cases, extreme muscular exhaustion can almost blot out gastric digestion.

In the Case 3 of gastric catarrh of more pronounced symptoms, gastric digestion is better than in the case of less pronounced symptoms. On referring further to my case-book, I find that in this condition there is no relation between severity of symptoms and degree of digestion.

The figures in the first case above do not quite agree with the findings of Zuntz; still, they are within measurable distance of his proteose-peptone ratio.

Considerable attention has been paid to the subject of parenteral administration of proteins. Some observers state that whilst the whole of the protein injected intravenously, subcutaneously, or otherwise, cannot be recovered from the urine, still the output of N in the urine is increased. The view is at present entertained that a large proportion of certain proteins introduced parenterally finds its way into the intestine, where it is either digested in the ordinary way or eliminated in the faeces. Indeed, the subject of intestinal secretion generally appears to be of considerable importance in connection with several problems of absorption and excretion. That individual cells of various tissues contain proteolytic enzymes has been definitely proved; but whether any considerable quantity of native protein is digested outside the alimentary canal in normal states of the organism at least is doubtful.

Proteins destitute of tryptophane are not capable of supporting nitrogen equilibrium. Tryptophane occurs in other interesting connections in the organism, more especially in connection with alkaline fermentation in the lower gut.

Before proceeding to study the catabolic changes which occur in the protein molecule, it is necessary to review some facts connected with the molecular structure of carbohydrates and fats, and some of the changes which are effected in these molecules. Von Bäyer's suggestion that the synthesis of sugar in plants commences with the reduction of CO_2 in the air, through the agency of the pigment chlorophyll in the presence of sunlight, is widely accepted. According to this view, the reduction product, formic aldehyde, undergoes condensation into a large molecule of sugar. Whilst the proof that this actually takes place has never been given, the hypothesis is so conformable to what we know of the chemistry of the bodies concerned that the conclusion that it is correct is almost irresistible.

The condensation assumed is a general reaction with aldehydes known as the aldol condensation, from aldol

$$\begin{array}{ccccccc} & & OH & & & & O \\ CH_3 & . & C & . & CH_2 & . & C \\ & & H & & & & H, \end{array}$$

the product of condensation of two molecules of acetic aldehyde

$$\begin{array}{ccc} & & O \\ 2CH_3 & . & C \\ & & H. \end{array}$$

The condensation of six molecules of formic aldehyde produces a hexose

$$\begin{array}{cccc} & O & & \\ 6H & C & = & C_6H_{12}O_6. \\ & H & & \end{array}$$

These reactions are almost isothermic, and easy of comprehension once formic aldehyde is produced.

In the animal organism we meet with carbohydrate in the forms of dextrose, lactose and glycogen. The condensation of glucose to form glycogen has been experimentally demonstrated in rabbits; but how the change is brought about remains still a mystery. It is probable that it is one phase of a reversible enzymic reaction.

All starches and vegetable sugars ingested undergo, partially in the mouth and fully in the upper segment of the small bowel, hydrolysis into dextrose. In the liver glycogen is hydrolysed into dextrose. Lactose is hydrolysed into dextrose and galactose. These last differ stereochemically:—

$$\begin{array}{ccccccccccl} & & OH & & OH & & H & & OH & & \\ CH_2OH & . & C & . & C & . & C & . & C & . & COH \text{ dextrose,} \\ & & H & & H & & OH & & H, & & \end{array}$$

$$\begin{array}{ccccccccccl} & & OH & & H & & H & & OH & & \\ CH_2OH & . & C & . & C & . & C & . & C & . & COH \text{ galactose.} \\ & & H & & OH & & OH & & H & & \end{array}$$

Carbohydrate combinations occur in certain proteins, in nucleic acids, and in certain fatty acid compounds. Nucleic acids in combination with some form of protein in cell nuclei, play perhaps the most important role of all the constituents of living protoplasm; their molecules invariably contain some form of carbohydrate, for the most part a pentose. Bang proved that the pentose was a constituent of the nucleic acid of pancreatic cells, and not of the associated protein, and a few years later Neuberg demonstrated the sugar to be a l-xylose. The same sugar has been found in the liver.

Xylose occurs in straw, etc., and forms the skeletal material of many plants; it is accordingly more or less outside the range of activity of plant ferments. Like other pentosans, xylose resists the action of alkalies, and requires for hydrolysis prolonged heating with mineral acids. It can be formed from dextrose by the degradation method of Wohler, wherein a carbon group is eliminated. The oxime of glucose is heated with strong NaOH and converted into the nitrile of gluconic acid. Further heating eliminates HCN, and leaves the pentose. By this general reaction a pentose may be converted into a tetrose, and finally, by repetitions of the process, formaldehyde may be reached.

Xylose may also be obtained from glucose: (1) By oxidation of the terminal alcoholic group in glucose into glycuronic acid; and (2) by subjecting the glycuronic acid to the action of certain bacteria, which split off CO_2, leaving l-xylose.

Starch and sugar enter so largely into the food of man that on the surface it might appear that the carbohydrates of the body are formed directly from these and from these only. This is not the case. In health the amount of sugar found in the blood practically never exceeds 0·2 per cent., or 10-11 grammes. In diabetes, patients have been known to eliminate 1,200 grammes of sugar in the day; and in experimental forms of the disease set up in dogs by extirpation of the pancreas, or by administration of the drug phlorrhizin, an even larger proportion of sugar has been excreted. Pflüger records an experiment in which, in two months, 3,000 grammes of sugar were excreted by a dog fed solely on protein food. The greater portion at least of this sugar must have been formed from something which was not carbohydrate. If not from protein, it must have been from fat. It is now definitely known that diabetics eliminate sugar after all administration of sugar is stopped, and that the ingestion of protein increases the output of sugar, whilst fat has no effect.

A large amount of information has been obtained concerning urinary nitrogen and sugar elimination in the meat-fed and fasting diabetic animal. The dextrose : nitrogen ratio (D : N) is an index to the quantity of sugar derived from protein. Nitrogen and dextrose double in quantity after ingestion of meat, but their ratio remains the same as in starvation. Since one gramme of urinary nitrogen represents 6·25 grammes of protein, and since there is simultaneously an average elimination of 3·65 grammes of dextrose in phlorrhizin diabetes, it is plain that the sugar derived from meat amounts to 58 per cent. by weight of the meat metabolised, and may contain over 52 per cent. of its available energy. Reilly, Nolan and Lusk have shown that the elimination of sugar takes place before that of the nitrogen. After the ingestion of 500 grammes of meat, the D : N ratio rose immediately from 3·4 to 1·9 and then fell, so that in successive three-hourly periods the ratio was 3·9, 2·9, and 2·9.

Minkowski showed that in depancreatised dogs, whether fasting or fed with meat, the elimination of dextrose : nitrogen (D : N) was as 2·8 : 1 The ratio in man is higher, the value assigned by Stiles and Lusk being 3·65 : 1.

Dextrose has been shown to be formed from asparagine, glycocoll, alanine, and other amino-acids. Neuberg showed that alanine is converted into lactic acid by hydrolysis with elimination of ammonia, which last is converted into urea. Lusk and Mandel showed that d-lactic acid is completely converted into dextrose in the organism:—

$$\underset{\text{alanine}}{CH_3.CHNH_2.COOH + H_2O} \longrightarrow \underset{\text{lactic acid}}{CH_3.CHOH.COOH} + NH_3.$$

It is probable that glutamic acid, aspartic acid, and serine yield glucose in the same manner.

Whilst the molecular weight and general structure of the carbohydrate molecule may remain the same, the smallest change in the space arrangement of the groups attached to the chain of carbon atoms is sufficient to alter profoundly the nature of the chemical activities. Pasteur showed that Penicillium glaucum assimilated only the right-handed tartaric acid from solutions of racemic acid, leaving the left-handed variety untouched. It is now known that both varieties are attacked, but that the velocity of the biological reaction in the case of the left-handed variety is so great relatively as

quite to overshadow the other reaction; moreover, there is evidence to show that the two varieties are attacked in a different manner. Again, it is possible to obtain one or other of the components of a racemic substance by employing appropriate organisms, *e.g.*, d-mandelic acid is obtained from the racemic substance by the growth of Penicillium glaucum, and l-mandelic acid by the growth of Saccharomyces ellipsoideus. When yeasts act on glucose, d-glucose only is converted into alcohol and CO_2, l-glucose remaining intact. Throughout the group of hexoses, only the d-isomeride is attacked. The four natural glucoses which are fermentable, viz., glucose, mannose, fructose, and galactose, are all d-compounds. Any species of yeast which ferments any one of the three sugars, dextrose, fructose, and mannose, will ferment the others. It has been demonstrated that the temperature coefficient of these fermentations is similar throughout. The ease with which these sugars can be converted one into another, through the influence of alkalies, has led to the assumption of an enolic form common to all —

$HOHC:COH.CHOH.CHOH.CHOH.CH_2OH.$

If H_2O be added to this it passes into an aldehydrol—

$HO.CHOH.HCOH.HOCH.HCOH.HCOH.CH_2OH.$

If, now, H_2O be taken away glucose appears—

$CHO.(HCOH)_4CH_2OH.$

There is no doubt that the transformation of sugar into alcohol and CO_2 is a succession of reactions, and possibly the formation of the enol is the first step. Afterwards either the same enzyme or a new enzyme breaks off the carbon atoms united by the double bond at the end of the chain. This last assumption is supported by the fact that certain bodies, such as gluconic acid, methyl glucosides, and a number of esters, differing from sugar only in the groups attached to the terminal carbon atom, are unfermentable.

Bacillus coli produces twice as much alcohol from mannitol as from glucose; it is reasonable to suppose that the difference is due to the group $CH_2OH.CHOH$, which is contained twice in mannitol, but only once in glucose.

Bertrand's sorbose bacterium has been shown to oxidise aldoses to the corresponding acids, whilst it converts alcohols into ketones; glucose becomes gluconic acid, *i.e.*, $C\begin{smallmatrix}\diagup O\\ \diagdown H\end{smallmatrix}$ becomes $COOH$; and sorbitol becomes sorbose, *i.e.*, $CHOH$ becomes CO.

It is unnecessary further to multiply examples in order to conclude that configuration in space of the elements of the carbohydrate molecule is of the first importance in determining the direction of many biological reactions.

Various animal and vegetable substances, whilst differing widely in physical characters, possess in common in their chemical constitution the radicals of fatty acids. Some of these are known as fats, some as oils, some as waxes, and some as "lipoids." Those members of the group which form foods are mostly esters of the triatomic alcohol glycerol. If solid at the ordinary temperature they are known as fats; if liquid, as oils. These esters may contain one, two, or three fatty acid radicals. The position of the fatty acid radical frequently leads to isomerism

$CH_2.OH$
|
$CH.OH$ glycerol.
|
$CH_2OH.$

$CH_2.O\ OC.C_3H_7$
|
$CH.OH$ monobutyrin, the α compound.
|
$CH_2\ OH.$

$CH_2.OH$
|
$CH.O\ OC.C_3H_7$ monobutyrin, the β compound.
|
$CH_2.OH$

The entrance of two fatty acid radicals gives —

$CH_2.O\ OC.C_3H_7$
|
$CH.O\ OC.C_3H_7$ dibutyrin, the $\alpha\beta$ compound.
|
$CH_2.OH.$

$CH_2.O\ OC.C_3H_7$
|
$CH.OH$ dibutyrin, the $\alpha\alpha$ compound.
|
$CH_2.O\ OC.C_3H_7$

The entrance of three fatty acid radicals gives—

$CH_2.O\ OC.C_3H_7$
|
$CH.O\ OC.C_3H_7$ tributyrin.
|
$CH_2.O\ OC.C_3H_7$

The H of the hydroxyl group in glycerol may be replaced by three entirely different fatty acid radicals, and this is the case in many naturally occurring fats. Again, phosphoric acid and fatty acids may be united to the same glycerol molecule, and since phosphoric acid is tribasic,

the acid hydroxyl groups not held by the glycerol may combine with alcohols, bases, etc. Further, we meet with mixtures of several glycerides with cholestrol, soaps, etc., so that there exists a large number of ill-defined fatty bodies with highly complex constitutions. Lastly, certain compounds of fatty acids containing phosphorus also contain nitrogen, and others a carbohydrate group.

Fatty acids are *saturated*, with the formula $C_nH_{2n}O_2$, an*d* *unsaturated*, with varying formulæ, but with the number of H atoms always less than that of the saturated acid containing the same number of C atoms.

In the saturated fatty acid series capric acid containing ten carbon atoms divides the series into two groups in respect of an important physical property. This acid and all the acids below it are easily distilled with steam, forming the "volatile fatty acids." The acids immediately above capric are volatile only in traces.

The unsaturated acids contain one or more pairs of C atoms united by double bonds. They are thus able to combine with halogens and become saturated. In the higher members of the series the double bonds may occur at different points in the chain, giving rise to different properties. The position of the double bond may be determined in certain cases by use of the fact that an unsaturated bond is liable to become saturated by the entrance of OH groups, whereby further oxidation breaks the chain at this point. Or the two unsaturated C atoms may link up two different arrangements of the same group, thus

$$\begin{array}{ccc} -C-H & \qquad & -C-H \\ \| & & \| \\ -C-H & & H-C- \end{array}$$

That the double bond in oleic acid is in the middle of the chain has been surmised from the following reactions –

Alkaline permanganate of potassium at high temperatures oxidises oleic acid to azelaic and pelargonic acids; at low temperatures to dioxystearic acid; the low-temperature reaction may be represented thus—

$$\begin{array}{ccc} CH_3 & & CH_3 \\ | & & | \\ (CH_2)_7 & & (CH_2)_7 \\ | & & | \\ H\ C\ OH & -H_2 \rightarrow & CO \\ | & & | \\ H\ C\ OH & & H\ C\ OH \\ | & & | \\ (CH_2)_7 & & (CH_2)_7 \\ | & & | \\ COOH & & COOH, \end{array}$$

and the high-temperature reaction thus

$$\begin{array}{ccc} CH_3 & & CH_3 \\ & & | \\ \cdot & & (CH_2)_7 \\ & & | \\ H\ C\ OH & -2H_2 \rightarrow & CO \\ | & & | \\ H\ C\ OH & & CO \\ | & & | \\ (CH_2)_7 & & (CH_2)_7 \\ | & & | \\ COOH & & COOH, \end{array}$$

the latter body splitting into –

CH_3 $(CH_2)_7$ $-COOH$ pelargonic acid, and $COOH-(CH_2)_7-COOH$ azelaic acid.

The action of ozone on oleic acid produces finally the same cleavage products.

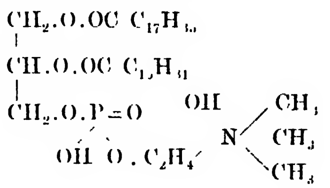
The interest of these reactions will be apparent when we come to discuss the oxidation of fatty acids in the body. On boiling fats with alkalies glycerol separates, and fatty-acid salts of the alkalies are formed as soaps. Under the action of the enzyme lipase contained in the alkaline pancreatic juice the same reaction occurs, but to a much less extent than was formerly supposed, in that the periodic entrance of acid chyme from the stomach lessens the alkalinity of the duodenal contents and thereby prevents the formation of soaps. Further, such soaps disappear somewhat after formation through hydrolytic dissociation. Sodium palmitate yields a clear jelly-like solution when treated with hot water. If this solution be diluted with water it becomes cloudy owing to liberation of free fatty acid and alkali. The free acid can be removed by shaking with toluene and estimated. The alkali set free can also be estimated by salting out the unhydrolised soap and free fatty acid together, dissolving the curd in alcohol and titrating with standard alkali. This hydrolytic dissociation can be prevented by the addition of alcohol or glycerol It can also be prevented by excess of alkali, as it is the liberated alkali which limits the dissociation. With volatile bases, such as ammonia, this limit falls, and the soaps are accordingly unstable.

Acids less saturated than oleic occur in the drying oils, in the liver of the cod, and the liver and other organs of mammals. Those found in animal tissues are mostly in combination with glycero-phosphoric acid. Drying oils take up oxygen when exposed to the air and become saturated as varnishes.

The more unsaturated bonds that exist in a fatty acid complex the more readily it takes up oxygen and the more unstable it is. It is a significant fact that in those tissues in which

fats are burnt, not merely stored, the fatty acids are unsaturated—that is to say, they have been prepared for combustion—whilst the stored fats are saturated and inactive. Rancidity in fats is produced by hydrolysis of the glycerides followed by oxidation of the free fatty acids in the presence of traces of moisture; lower volatile and oxyacids appear in the process. Rancidity in butter prevents complete hydrolysis in certain cases of gastro-intestinal catarrh, as may be determined by estimation of the glycerides in the faeces.

Certain compounds of fatty acids containing phosphorus and nitrogen, and others containing nitrogen, are met with. To the first class belongs lecithine, which was prepared by Diakonow from yolk of egg by shaking with ether. Lecithine is optically active owing to its unsymmetrical glycerophosphoric acid. Erlandsen prepared lecithine from heart muscle which possessed an iodine value of 110. Glycerophosphoric acid is obtained as a barium salt when lecithine is saponified with baryta; this salt is soluble in water, but insoluble in absolute alcohol. The reaction is not quantitative. Lecithine gives Pettenkofer's reaction with H_2SO_4 and sugar through its contained unsaturated fatty acids. Hoppe-Seyler hydrolysed lecithine and studied the cleavage products, which he found to be fatty acids, glycerophosphoric acid and choline. He concluded that in glycerophosphoric acid, through one of the OH groups of glycerol, an ester of phosphoric acid is formed in which two alcoholic OH groups are free and two acid OH groups are free. Two fatty acid radicals form ester connections with the alcoholic hydroxyls, and choline unites with one of the acid hydroxyls. Choline could unite with an acid OH by its alcoholic OH or by its basic OH The former union is accepted and the structure of lecithine is represented as—



in which other fatty acid radicals may take the places of those in the formula.

The fatty acids recovered from lecithine by Hoppe-Seyler were thought to be stearic, palmitic and oleic. But several different findings have appeared in recent years for the iodine values of the fatty acids of lecithine. Indeed, it is problematical if such a body as the above definitely exists, since neither the yield of choline nor of glycerophosphoric acid is constant.

By the methods of Farnsteiner and Varrentrapp non-volatile fatty acids can be separated into liquid unsaturated and solid saturated. In a general way the lead salts of unsaturated acids are soluble in ether, whilst those of saturated acids are insoluble.

Saturated acids obtained from the lead salts insoluble in ether may be resolved into their constituents by fractional precipitation of barium or magnesium salts and removal of the free acids by HCl and petroleum ether. Or they may be resolved by fractional distillation of their ethyl esters in vacuo.

Unsaturated acids may be obtained from the lead soaps soluble in ether by bromination, or their identification may be established by oxidation of the acids formed.

Some of the characters and properties of fats I have dealt with elsewhere

The fats of animals are mostly the fats of their foods. The fat of an individual may be altered by changing the fat in its food. The fat of an animal fed on linseed oil contains linolein. Fats and oils occur in plants in ripe seeds. Seeds before ripening contain large quantities of carbohydrates but no oils. It is reasonable to suppose that the fats are formed from the carbohydrates. The formation of fatty acids from carbohydrates has been proved in animals. To accomplish this it would appear that an alcoholic OH is reduced and its O transferred to another carbon atom thus—

$CH_2OH.CHOH.COH \rightarrow CH_3.CHOH.COOH.$

Nef showed that the same treatment with weak alkalies produces lactic acid from glyceric aldehyde and glucose. Embden produced lactic acid from glycogen (hence from glucose) by perfusing a liver rich in glycogen. Conversely, Mandel and Lusk have shown that lactic acid administered to a diabetic animal is converted into glucose. Accordingly lactic acid is an important intermediate product in the metabolism of carbo-hydrates.

Lactic acid is produced from sugar by the enzymes of various bacteria. Pasteur showed that certain bacteria which effect the butyric acid fermentation of sugar produce butyric acid from lactic acid as readily as from sugar. Nencki explained the synthesis necessary to convert lactic acid into butyric acid by assuming that lactic acid breaks down into the lower aldehyde (acetaldehyde), hydrogen and carbon dioxide. Two molecules of aldehyde condense

to form aldol, a four-carbon chain, and this when reduced and oxidised yields butyric acid —

$$\begin{array}{ccccccc} CH_3 & & CH_3 & & CH_3 & & CH_3 \\ | & + & | & \rightarrow & | & & | \\ COH & & COH & & COH & & CH_2 \\ & & & & | & \rightarrow & | \\ & & & & CH_2 & & CH_2 \\ & & & & | & & | \\ & & & & COH & & COOH. \end{array}$$

This synthesis would appear to be good for the formation of acids with six, eight, etc., carbon atoms, but not for acids with five, seven, etc., carbon atoms. It is significant in this connection that fatty acids with more than six C atoms produced in nature have an even number of carbon atoms attached in a straight chain.

Pinkus and Wohler suggested that in the formation of lactic acid from glucose glyceric aldehyde was first formed

$$CH_2OH.(CHOH)_4.COH \rightarrow 2CH_2OH.CHOH.COH$$

then pyruvic aldehyde

$$CH_2OH.CHOH.COH \rightarrow CH_3.CO.COH$$

and finally lactic acid

$$CH_3.CO.COOH \rightarrow CH_3.CHOH.COOH.$$

This fascinating theory appears to derive some support from such evidence as: (1) Dextrose yields the osazone of pyruvic aldehyde when treated with alkalies and phenyl hydrazine: (2) Alkalies convert pyruvic aldehyde into lactic acid; (3) Dihydroxy acetone on distillation with H_2SO_4 yields pyruvic aldehyde: (4) The work of Windaus suggesting the view that disaccharides are formed from glucose by synthesis from glyceric aldehyde and lactic acid.

ENGINEERING OPENINGS IN CHINA.

Gold is found in many parts of the province of Szechuan, China, but not always in paying quantities. According to a recent report from Chungking, the most important mine in Szechuan that has thus far been opened is located at a very mountainous place called Maha, which lies in the south-western corner of this province about fifty miles north-west of Ningyuanfu. The Government is very anxious to develop the Maha mine to the fullest possible extent, and is now undertaking a thorough reorganisation. Two Chinese engineers, who studied mining engineering in Belgium, are employing a corps of trained assistants and about 1,200 miners in the mining work at Maha. Both the Government at Peking and the provincial authorities are giving them every encouragement, and there is reason to believe that this project will finally succeed. New mining machinery is needed to carry on this work to the best advantage. This opportunity is exceptional, inasmuch as the installation of a plant at Maha would doubtless result in further business, since not only gold is found in the western part of this province, but antimony, iron, lead, silver, and copper also occur in considerable quantities, and will be mined eventually by up-to-date methods.

H.M. Consul-General at Yunnan-fu remarks that the great drawback to British trade in the province of Mengtsu hitherto has been the lack of any British firm to represent United Kingdom manufacturers and push the sale of their goods; but there is a good prospect of this deficiency being remedied in the near future. The present time, he says, is exceptionally favourable for such an enterprise, as the two German firms which have hitherto supplied local buyers with machinery, etc., can now obtain no further supplies, and the Chinese would welcome the establishment of a British firm in Mengtsu. There are inquiries for irrigation pumps, electric light machinery, flour and rice mills, material for the installation of waterworks in Yunnan-fu, locomotives and trucks for the Pishihchai Railway, and other items. but these can only be dealt with by a man on the spot who is prepared to make a contract for the goods delivered c.i.f. at Haiphong, possibly assist to some extent in their erection, and arrange the question of exchange.

According to a recent official report, the district of Tzeliuching, which lies in the south-central part of Szechuan, some fifty miles north of Suifu, is the most important industrial centre in West China. This is true not only as regards its present state of development, but also as regards its potentialities and possibilities. Tzeliuching at no distant date will place larger orders for foreign machinery than any other city in this part of China. Machines for drilling new wells, for pumping up the brine, and for evaporating the salt are of first importance. Simple hoisting engines to supplant the water buffaloes should enjoy a large sale. Gas stoves and burners and engines using gas for fuel could also be introduced. As the salt wells are operated night and day, there is an excellent opportunity for the sale of electric-lighting plants. Telephone apparatus is also in demand, and mine pumps and machinery are needed in the coal-fields.

Writing on the resources of the Kaihsien District, the American Consul at Chungking, Szechuan Province, says that while there is not much chance of introducing textile machinery at the present time, if factories are started and the industry develops to any extent, there ought to be a market for cheap looms of simple construction. Mining machinery might even now be sold to advantage, both for coal and iron, and a modern smelter might be established very profitably at Ma-chia-kou or Wen-tang-ching. With the cheap labour and the extensive deposits of iron and coal, there is no reason why the Kaihsien District should not become in the course of time an important manufacturing and industrial centre.

He also points out that, as the district about Chengtu develops, there will be an increasing demand for foreign machinery. Mining machinery is needed in the development of the region west of Kwanhsien, where lead, coal, silver, and copper deposits are said to be extensive. There is also a demand for machinery for the scientific refining of salt and sugar, and for the manufacture of paper, shoes, soap, candles, and many other articles. Modern sawmill machinery will eventually be introduced. Machinery for silk and cotton weaving could be used to advantage; much of the Thibetan wool that comes from Tachienlu to Chengtu could be made into fabrics at the latter city, where labour is cheap and water-power available.

THE CHANK FISHERIES OF INDIA.

Mr. James Hornell, the superintendent of pearl and chank fisheries to the Government of Madras, has written an interesting monograph on "The Sacred Chank," from which the following is taken:—

Five distinct chank fisheries are carried on at the present day in India. Ranked in the order of their importance they are: (a) Tinnevelly (usually called the Tuticorin fishery); (b) Ramnad (with Sivaganga); (c) the Carnatic coast (South Arcot and Tanjore); (d) Travancore; (e) Kathiawar - to which is to be added a large one in the north of Ceylon.

Without exception, the chank fishery in each of these localities is considered a royal prerogative, the monopoly of the Government; in practice this prerogative is variously exercised. In Tinnevelly the Madras Government works the fishery departmentally through an officer of the Fisheries Department. On the Carnatic coast the shells are either (in Tanjore) bought at fixed rates from the fishermen by the Customs Department on behalf of the Fisheries Department, or else (in South Arcot) the exclusive right to collect is farmed out to a renter for a term of years. The latter administration of the prerogative is also in force in Okhamandal (Kathiawar), where the Gaekwar of Baroda exercises sovereign rights in the local fishery. In Ceylon the renting system was in force until 1890, when it was abandoned in favour of an export duty. In Travancore the dues of the Government are collected in the same manner as in Ceylon. The Tinnevelly chank fishery was until lately the only one that was carried on systematically and with a definite organisation.

The more satisfactory course of the 1913-14 fishery over those of the two preceding seasons was due chiefly to the very favourable weather that prevailed from the beginning of January to the middle of May. The fishing grounds exploited during the season were those lying north-east and east of Tuticorin. The particular beds that gave the greater bulk of the shells were: (a) Vattikal Piral, (b) the neighbourhood of the Nadu Thundam par, and (c) more especially the ground called Koli Kunju-tavu, from which alone 65,086 chanks were fished.

As the beds fished had received much attention from the diving staff in 1910-11, but none in 1911-12 or 1912-13, the shells were most satisfactory in size and quality. The proportion of "wormed" shells was particularly low, being only 3,551 out of a total take of 245,308, as against 13,133 out of 158,704 in the preceding year, when beds that had not been fished for a number of years received attention. This emphasises the value of fishing the beds at regular and not too long intervals; failure to fish any bed at least once in three years entails the presence of an undue proportion of "wormed" shells. The shells fished were, as usual, graded into nine sizes—beginning with shells 4 in. or more in diameter, and diminishing by ¼ in.—by means of gauge boards, each size being stored in a separate bin.

IMPROVING TRADE PROSPECTS IN YÜNNAN PROVINCE.

In a general way trade prospects in Southern China seem to be improving. Conditions along the West River in Kwangsi Province are reported by Chinese middlemen as considerably improved compared with three months ago. There is an increased demand for cotton piece goods, and some of the considerable stocks on hand in Hong-Kong are being absorbed by this up-river trade. Cotton yarn prospects also are improving. The kerosene trade is somewhat better, though piracy has been interfering with it to a very material extent.

In Yünnan Province correspondents report considerable activity in prospect. A waterworks system for Yünnanfu is now being seriously considered, and a proposition from a British firm in Hong-Kong seems likely to be accepted. It is proposed to spend about £27,000 upon the initial enterprise. Of this amount the Government will furnish one-third and private capital two-thirds.

Talifu is agitating for an electric lighting system, and a Chinese company is being formed to furnish it. So far, capital is somewhat reluctant to come forth, writes the United States Consul-General for the Yunnan Province; but inasmuch as the city is an important one, and other Chinese cities in the province are enjoying satisfactory electric light services, with profit to all concerned, it seems probable that the new concern will be effectively organised. Modern bridges are being called for in various parts of the province, and Hong-Kong firms in a position to contract for such work have a number of propositions under consideration. However, in view of high freight rates and the increased cost of all structural steel, it is doubtful if any such work will be done for the present.

In general, the condition of Yünnan Province is reported as prosperous. The spring harvest is reported as eight-tenths good, and there is increased production of cotton over considerable areas. Some opium is still cultivated in remote places, in spite

of the inhibition of the crop by the Government at Pekin. There is considerable interference with the trade of the province by the war. The export of antimony, copper and spelter is practically stopped because, as contraband of war, the French authorities will not transport these minerals through Indo-China except for themselves and at substantially their own prices. The export of tin is also interfered with in the same way, though the export is continued by special arrangements, including the permission necessary to re-export it from Hong-Kong after refining.

SEPARATING OIL FROM WATER OF CONDENSATION.

A novel method of separating oil from water of condensation, now being used in some large mining plants in Germany, is described in *Cassier's Engineering Monthly*. In this arrangement the water is led to a deep well which is vertically divided into three compartments of equal capacity. The water of condensation, rich in oil, flows into one compartment, and is then led through pipes from the deepest part of the well into the second compartment, whence it passes into the third compartment, and is finally delivered by a centrifugal pump whose suction is also at the deepest part of the well. When the water is admitted to the well, the oil in it is either in drops or in emulsion. In the well, when the water is in a state of rest, the oil in drops separates, and can be easily collected on the surface. This oil is pure because of the heavier impurities having settled down to the bottom of the well, and can, therefore, be again used for cylinder lubrication. If, however, the water of condensation is intended for use as boiler feed-water, it must be freed also from the oil in a state of emulsion, and this is done by means of an electrolytic oil separator. In this case the water containing the oil is supplied by a centrifugal pump and first passes into one of the compartments, where it is fed between electrodes, the separation of the oil taking place under the action of the electric current. Since, however, the water of condensation, apart from the oil it contains, is a very bad conductor of electricity, its resistance is decreased by the addition of a solution of soda. It has been found that with current costing $\frac{1}{4}d.$ per kw. hour, the cost of purifying the cubic metre (say, 35·3 cubic feet) of water per hour amounts to less than one-sixteenth of a penny.

DIAMOND INDUSTRY IN THE NETHERLANDS.

The diamond trade, one of the most important of all Dutch industries, experienced in 1914 one of the most trying years in its history. Exports to the United States, its principal market, heavily declined, and general conditions were unfavourable. The increased duty put upon both rough and polished diamonds by the American Tariff Act of 1913 and the financial situation contributed to the decrease.

There was another disturbing factor in the early part of the year, that is, dissatisfaction with the business methods of the Antwerp Syndicate, which handled the supply of German rough diamonds. In April, however, the London Syndicate assumed control, the change bringing about an immediate feeling of relief. Shortly thereafter, when the conference of representatives of the principal mining concerns at London decided to limit production, a revival of trade was confidently looked for. When the war broke out, however, diamonds almost ceased to be articles of commerce, the cutting and polishing factories practically closing down. Trade was stagnant, and so remained until near the end of the year, when operations were resumed in a few establishments on a diminished scale. Work undertaken before the war had to be completed, but only a few concerns did business of any importance. True, there were transactions among the diamond brokers and dealers, but none of consequence, and the strenuous efforts of leading men in the trade to maintain a scale of prices came to naught.

It is hardly possible that there can be a revival in trade during the continuance of the present war; but in the best-informed circles the feeling prevails that the return of peace will mean new life to the trade. It is within the memory of many that after the Franco-German War it experienced a long period of prosperity. The South African War of 1899 brought hard times, but with the declaration of peace there was a surprisingly quick revival, which was only broken by the general financial crisis of 1907.

According to a report by the United States Consul at Amsterdam, the diamond industry gives employment to more than 10,000 working people—sawyers, cleavers, polishers, cutters, etc. Of this number about 9,800 are members of the Amalgamated Union of Dutch Diamond Workers, a beneficial organisation, the records of which show that at the beginning of 1914 over 5,000 of its members were out of employment, and that during the seven months preceding the war the average of unemployed was nearly 4,000. When the war began about 80 per cent. of the employees were out of work, and the remainder were on short time.

The following table shows the value of shipments of diamonds to the United States from January 1st to July 31st, and from August 1st to December 31st, in 1913 and 1914 :—

Kinds.	1913.		1914	
	Jan.-July.	Aug.-Dec.	Jan.-July.	Aug.-Dec.
	£	£	£	£
Rough .	145,611	51,420	55,766	33,741
Polished	1,580,085	457,055	899,453	132,124

In analysing the foregoing figures it might appear that the European war had but little influence on the movement of diamonds from Amsterdam to the United States, the decrease after August 1st not being so pronounced as would naturally be expected. In this connection it should be remembered that among the thousands of Belgian fugitives arriving at Amsterdam at the time Belgium was invaded were many diamond dealers, who, after bringing their stocks to Amsterdam, shipped them to the United States to be sold for the best obtainable prices.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Current Conditions.—The busiest manufacturers at the present time are clearly those making goods for the direct purposes of war, be those goods what they may. Next to them rank a not inconsiderable number of producers of necessary articles, who have gained more from the suspension of foreign competition than they have lost from the total restriction of markets. Makers of goods of which the purchase can be indefinitely delayed, and manufacturers of fancy or luxury articles, have much less employment, and it cannot be a serious misstatement to suggest that production of such goods has decreased by at least one-half. Comparatively little energy is going into the production of frippery. The great bulk of the textile work done is unquestionably in response to the most solid requirements. The armies are being equipped and the home civilian population is being clothed in mainly plain and durable goods, and export is limited to the natural needs of those who rely upon British industry.

Economy in Clothing.—In their own experiences, manufacturers see little of the unthrift that is sweepingly charged against the home population. Certainly the buyers with whom they come into contact exhibit the customary cautiousness in the face of high prices, and are well disposed to defer any operations that can excusably be put off. The economy in clothing that is being enjoined upon the nation at large is being fairly well observed at their end of the trade. For instances of extravagance one has commonly to look to the other end, through which goods have to pass upon their way to the consumer. Manufacturers cannot avoid such guilt as there may have been in playing up to the insatiable demand for novelty of appearance, even at the cost of the sterling quality of the goods. The taste for two or three cheap articles at the price of a single good one has not been wholly of their making, and now that economy is incumbent upon everybody they would not be sorry to find the consumer realising that the cheapest thing to buy is commonly the very best that can be bought.

Comparative Values.—The cheapest possible article of any largely sold kind of goods is usually the one carrying the smallest loading of profit. The article that is made to squeeze into some arbitrary limit of price brings the lowest percentage to maker, wholesaler and retailer alike. All three exert themselves to the utmost to make at least the show of "exceptional value," but the result is seldom economically satisfying. More is taken out of the value-in-use than out of the profitable margins. To cite an instance from practice obtaining before the war, some particulars of the cost and selling prices of certain German-made hosiery may be given. It was possible in certain neighbourhoods to buy knitted undergarments at 1*s*. 11*d*. retail, or 7*d*. more than the price received by the manufacturer. The next quality sold at 2*s*. 11*d*., or 1*s* 5*d*. more than the prime cost. One garment cost 2*d*. more than the other and sold 1*s*. dearer. The disparity is pretty formidable, but it is a matter of practically universal experience that the difference was money well spent. The 1*s*. 6*d*. garment at 2*s*. 11*d*. was a more remunerative investment than the 1*s* 4*d*. garment at 1*s* 11*d*. In its turn the latter of the two was again less advantageous than some at a higher cost. The cheapest of all was the one selling most largely of any, for naturally its patrons were the first to want new clothing, but in grasping at the shadow of cheapness they lost its substance. Although the instance is taken from the past, precise parallels could be drawn from the present.

The Supply of Labour.—It may henceforth become more urgently desirable to recall women to the mills, and the National Register ought to be of service in ascertaining the whereabouts of competent married women. There is some reason to suppose that a number of ex-operatives are more willing to undertake home work than factory work, and it is to be suspected that not all of them have avowed their skill in spinning and weaving. The shortage of operatives is most felt of course where business is briskest. Rochdale, which has been renewing its old position in the flannel manufacture, has drawn upon the Belgian refugees, the Isle of Man and the West of England, for women-workers. Want of hands is felt severely even in Nottingham and Leicester, towns where the industrial conditions are far from unpleasant, and where labour is normally plentiful. Greater difficulty is caused by the withdrawal of skilled mechanics who are relied on to keep intricate machinery in running order, and their replacement seems to be an insoluble problem. It takes a considerable emergency to move any large number of textile workers from place to place, and even collapse of the local trade will not always drive them afield. However, a certain movement of the population has occurred in times past, as when numbers of Coventry weavers made their homes in Lancashire, and Norwich weavers in Yorkshire, towards a century ago.

Cotton Waste in India.—An interesting beginning in the transference of German business is being

made in Bombay with the aid of machinery now upon order in Lancashire. The German mills have been the chief destination for the cotton waste which for a year past has been accumulating upon Bombay spinners' hands. The price has fallen to a nominal amount, and the presence of large supplies of raw material lends attraction to what is not normally a highly remunerative business. Had German profits been high, there must have been more competition from Lancashire, for the main difficulty encountered by various manufacturers making the attempt has been to get any adequate return for their labour. It is apparently in blankets and heavy goods that a beginning is to be made in India, and in these the troubles and risks of the finishing process are less than in the lighter flannelettes.

Remedying Oil Stains.—Stains made by the dropping of lubricating oil upon textile materials are a prolific source of loss, and are difficult to avoid. The damage done is naturally greatest in the case of light-coloured goods, and it is aggravated commonly by dirt coming from the bearings of the machinery It has, however, been found that oil, itself colourless, is capable of giving rise to dark stains, which develop gradually upon exposure to light. The action is due to the oxidation of free hydro-carbons present in some oils and not present in others. To test the liability of oils to darken in sunlight is a matter of three or four months, and to hasten the process a lamp test has been devised by an American chemist. Mr. T. T. Gray employs a Cooper-Hewitt quartz lamp giving a light rich in the ultra-violet rays, and by exposing samples at six inches distance from the light useful indications are obtained in half an hour. The method is comparative: strips of cloth impregnated with oil of known quantity are tested against the unknown, and certain oils which do not darken in sunlight tests are found to take a yellow-brown cast under the lamp.

The Strengths of Fabrics.- In this country the testing of the tensile strength of fabrics is influenced by the requirements of the Government departments who happen to be the principal buyers of cloth made to standards of strength. For the rest, practice has been determined by the example of institutions like the Manchester Chamber of Commerce Testing House and the Bradford Conditioning House. In America the framing of specifications has been undertaken by a committee, primarily with a view to standardising tests for the now considerable quantities of cotton cloth used as a basis for pneumatic tyres. Important variations of result are obtained accordingly as the atmospheric humidity changes, and although the American Society for Testing Materials has provided for the preliminary drying of the specimens in an oven, it has not provided that the test of strength shall be conducted within a controlled atmosphere. It is required simply that the breaking-strain shall be read within thirty seconds of removal from the oven. In the particular case the difficulty of measuring the fabric "as it lies flat without tension upon a smooth surface" may be at its minimum, but the scrupulously exact measurement of fabrics at large might involve the fixing of a standard of tension. The specifications are not put forward as final, but are meant for amendment after one year's practical experience of them has been gained. The framers have been at some pains to insist that measurements shall be made on the average of a whole piece, the width and number of threads being determined by five tests at intervals. The enlarged scale of Government purchases may have done something to reconcile manufacturers to rigid tests other than those of length, width and weight, but it would be impossible to say that compliance with arbitrary and high-pitched standards of strength has been at all popular with manufacturers hitherto. The explanation is probably to be found in the selection of features for testing. At all events, in articles of dress it does not follow that the one which resists the highest tensile strain is *ipso facto* the strongest in wear, because wear does not consist entirely of the application of extreme pulls. For the regular purposes of commerce the sufficiency of the tensile strength can be determined by thumb tests The fabric is strained across the thumbs by steady pressure and the result is observed. In the case of cloth brought under iron regulations, or tyre fabrics intended to withstand an internal pressure which would burst some steam boilers, matters are on a different plane; and it would seem that we are to have more fabrics requiring to be made to absolute standards of tensile strength. The development of aerial navigation is adding to the number, and so long as standards are not made artificially difficult of attainment, little is to be said against their establishment.

GENERAL NOTES.

Awards to British Exhibitors at San Francisco.—The preliminary list of awards at the Panama-Pacific Exposition, San Francisco, has been received by Mr. W. A. M. Goode, who acted as Hon. Secretary of the British Committee which arranged for participation for exhibitors from this country. Despite the war and lack of Government support, British manufacturers are stated to have received more awards than any other foreign exhibiting nation. The Grand Prix has been granted to the following British firms: Messrs. Joseph Baker & Sons, Ltd. (bread-making machinery); Messrs. John S. Brown & Sons, Ltd., Belfast (linens): Mr. Bernard Moore, Stoke-on-Trent (pottery); the Gas Light and Coke Company, London; Messrs. Gibson & Sons, Ltd., Burslem (earthenware); and Messrs. Gordon's Dry Gin Company, London. The Medal of Honour has

been awarded to The Mersey Docks and Harbour Board, Liverpool; Lady Egerton (hand-made laces and embroideries); Messrs. R. H. and S. L. Plant, Longton (pottery); Messrs. Booths, Ltd., Tunstall (pottery); the Ashby Potters Guild, Woodville (pottery); Messrs. Birks, Rawlins & Co., Stoke-on-Trent (porcelain); the Ceramic Art Association, London (pottery); Messrs. The Tintometer, Ltd. (colour registering); and Messrs. Lips, Ltd. (safes and locks). The Gold Medal has been awarded to the Magnesite Syndicate, Ltd., London; the Vizianagaram Mining Company, Ltd., London; Messrs. William Livingston, Lurgan, Ireland (linens); Messrs. Ian Barry (Bergdahl walnut); the Stonehenge Woollen Industry, Lake, near Salisbury; the Fisherton de la Mere Embroidery Class, Wiltshire; Messrs. Worsnop & Co., Halifax (battery); Messrs. Riordan & Co, London (life-saving waistcoat); Messrs. Baker & Co., Fenton (pottery); Messrs. Myott, Son & Co., Cobridge (pottery); Messrs. William Adams & Co., Tunstall (pottery); Messrs. F. Fielding & Co., Stoke-on-Trent (earthenware); Messrs. A. J. Wilkinson, Burslem (earthenware); and Messrs. W. H. Goss, Stoke-on-Trent (porcelain). A Silver Medal has been awarded to the Loch Fyne Kintyre Lace Classes, Tarbert, Loch Fyne. A further list of awards is expected in the near future.

Far-Eastern Coffee Supply.—The Bureau of Agriculture of the Philippine Islands at Manila announces that a determined effort is to be made by the Government of the territory to rehabilitate the coffee production of the islands. The coffee supply of the Far East at present is not satisfactory, and there is a ready market at good prices in neighbouring countries for all the coffee the Philippines are likely to produce for some time. That the Philippines can produce excellent coffee is well known. At one time the export of coffee was one of the principal items in the list of products sold abroad, and Batangas Province, the centre of the industry, was one of the most prosperous provinces in the archipelago, the city of Yipa especially being known as an important coffee centre. About 1890, however, the coffee trees were attacked by various blights and rusts, and the industry was ruined in the course of a few years. The Philippine Government has been experimenting for some time with various varieties of coffee with a view of introducing a blight-resisting variety in this same province, and after several years of experiment it has found that the "robusta" variety is immune to the ravages of insect and other prevailing pests. The Bureau of Agriculture has prepared 3,500,000 plants in seed beds. It plans to set out trees covering 10,000 hectares (about 24,710 acres) in five years, with 2,000 coffee trees per hectare (about 810 trees to the acre). It is anticipated that at the end of that period Batangas Province will have at least 20,000,000 coffee trees in bloom. The trees are to be distributed free. They have been grown and experiments have been carried on under the supervision of experts from Java.

Japanese Knitting Yarns in Hong-Kong.—For the first time in the history of the trade, according to the American Consul-General at Hong-Kong, Japanese knitting yarns are cutting into the American trade in such yarns in Hong-Kong and in the China field generally. In the Yangtsze Valley the import of Japanese knitting yarns is understood to be increasing at a rapid rate. In Hong-Kong and South China the increase is not so rapid, and in some respects it is not at all certain that it will be permanent. However, the Chinese factory people have been buying some of the Japanese yarns, and are slow about taking delivery of American yarns heretofore ordered by them, giving rise to a rather well-founded suspicion that they are looking into the possibility of using the cheaper Japanese materials. It is likely that at best the trade in Hong-Kong and in China generally will be upset for some time to come. The Japanese are turning out very fair yarns made of American and Chinese cottons at c.5 to c.10 local currency per pound cheaper than American yarns of the same count. These yarns are not so good as American yarns, and the goods made from them are not as good as those manufactured from the American yarn, but the yarns and the goods make a very good appearance, and for the time being, at least, are securing increasing trade. The Japanese yarns now coming into the market are attractive in appearance and run well in the machines.

Potash in the Philippines.—It has been found that the ash of the seaweed collected on the shore of Manila Bay in Tondo yields 15 per cent. of potash. This discovery, according to a report by the Correspondent at Manila of the United States Department of Commerce, has aroused considerable interest, owing to the war-time scarcity of potash. No data exist to show the exact amount of seaweed available, but it is known in a general way that it is abundant. Explorations and further experimentation will be conducted by the Government.

Tobacco Crop of the Cavalla District.—Some details of the tobacco crop of the Cavalla district in 1914 are given by the British Vice-Consul at Cavalla, in a report which is included in a general report on the Salonica district, just issued by the Foreign Office. It appears that last year the crop was abundant, being estimated at about 16,000,000 kilogrammes for the districts of Cavalla, Sarishaban, Drama, Pravista, Buk, Serres, etc. Connoisseurs, however, consider that the 1914 crop leaves much to be desired as to quality, and they estimate that it contains about 60 per cent. of inferior tobacco. This tobacco will be manipulated during the course of 1915, and will not be ready for export before the end of the year. Leaf tobacco is the principal, indeed almost the only, article of export from the port of Cavalla.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

COLONIAL SECTION COMMITTEE.

The following is the list of the Colonial Section Committee, as appointed by the Council:—

Dugald Clerk, D.Sc., F.R.S. (Chairman of the Council).
Lord Blyth (Chairman of the Committee).
Marquess of Aberdeen and Temair, P.C., K.T., G.C.M.G., G.C.V.O.
Sir John Anderson, G.C.M.G., M.A., LL.D.
Earl Brassey, G.C.B., D.C.L., LL.D.
Byron Brenan, C.M.G.
Richard Ernest Brounger.
Sir Thomas Fowell Buxton, Bt., G.C.M.G.
Sir Gilbert Thomas Carter, K.C.M.G.
Hon. Sir John A. Cockburn, K.C.M.G.
Captain R. Muirhead Collins, R.N., C.M.G., Official Secretary to the Australian Government in Great Britain.
Edward R. Davson.
Edward Dent.
Right Hon. Sir George Goldie, K.C.M.G., D.C.L., LL.D.
W. L. Griffith.
Lord Inchcape, G.C.M.G., K.C.S.I., K.C.I.E.
Hon. J. G. Jenkins.
Sir Charles Prestwood Lucas, K.C.B., K.C.M.G.
Hon. Sir Peter McBride, Agent-General for Victoria.
Hon. Sir John McCall, M.D., LL.D., Agent-General for Tasmania.
Hon. Thomas Mackenzie, High Commissioner for the Dominion of New Zealand.
Hon. Sir Newton James Moore, K.C.M.G., Agent-General for Western Australia.
Sir Montagu F. Ommanney, G.C.M.G., K.C.B., I.S.O.
George Robert Parkin, C.M.G., M.A., D.C.L., LL.D.
Sir Westby B. Perceval, K.C.M.G.
Sir Robert W. Perks, Bt.
Hon. Sir George Halsey Perley, K.C.M.G.
Hon. Sir Cornthwaite Rason.
Right Hon. Sir George Houston Reid, G.C.M.G., D.C.L., K.C., High Commissioner for Australia.
Viscount Ridley.
Right Hon. Sir Joseph West Ridgeway, G.C.B., G.C.M.G., K.C.S.I.
Major Sir Thomas Bilbe Robinson, K.C.M.G., Agent-General for Queensland.
Lord Sanderson, G.C.B., K.C.M.G.
Hon. William Philip Schreiner, K.C., C.M.G., High Commissioner for the Union of South Africa.
Sir Thomas Sutherland, G.C.M.G., LL.D.
Carmichael Thomas.
Sir William Hood Treacher, K.C.M.G.
Sir Charles Rivers Wilson, G.C.M.G., C.B.
George Wilson, C.B.
Hon. Bernhard Ringrose Wise, K.C., Agent-General for New South Wales.
Sir John Wolfe-Barry, K.C.B., F.R.S.
Hon. F. W. Young, LL.B., Agent-General for South Australia.
S. Digby, C.I.E. (Secretary).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

FOODSTUFFS.

By David Sommerville, B.A., M.Sc., M.D.,
Assistant Professor of Hygiene and Public Health, King's College, London.

Lecture II.—Delivered May 3rd, 1915.

Modern work on enzymes has produced the view that the activities of these substances—if special substances there be—are of the order of those of catalysts, *i.e.*, in the presence of such substances the rate of a particular chemical reaction is increased; but the reaction is not initiated. In many biological, as distinguished from purely chemical, reactions one is struck by the ease displayed in the mode of producing the result. In the animal body raw protein is smoothly and rapidly converted into amino-acids at body temperature; in the chemical laboratory the strongest acids at boiling temperature are needed to produce this result.

Since the days of Berzelius the subject of catalysis has been eagerly discussed, and the fact that catalysts are found at the end of the reaction unchanged, except in certain cases in which they are destroyed by subsidiary reactions, has been deemed sufficient to place them in a class apart.

Catalysts are definite chemical compounds: enzymes are not yet known to be such. Catalysts, in a large number of reactions at least, form intermediate compounds during the course of the reaction. That some form of intermediate reaction occurs between the enzyme and substrate is a view held by most.

In those biological reactions with which we are at the moment concerned, one or more of the interacting bodies is always colloidal, and all enzymes are regarded as colloids. This leads to a word concerning the colloidal state. Colloidal solutions possess peculiar physical properties inextricably bound up with the enormous surface presented by the particles. If a liquid be contained between two parallel plates and one of these be moved with a constant velocity in its own plane a certain force is

required which depends on the velocity, the surface and distance of the two plates, and on the temperature and nature of the liquid. The force required to move a plate of unit surface separated from another plate of the same size by a layer of liquid of unit thickness at unit velocity is known as the viscosity coefficient. Colloidal solutions may be divided into two classes if the increase of viscosity compared with that of the continuous phase (solvent) be made the basis of classification. One class presents a viscosity only slightly higher than that of water (metal and sulphide solutions). The other, the organic colloids (albumin, gelatin, etc.), presents a marked increase of viscosity. In those solutions presenting a low viscosity the disperse phase is present as solid particles; in those with high viscosity the disperse phase is liquid. Albumin solutions consist of a dilute solution of albumin, in which are dispersed globules of a more concentrated solution. Systems of solid particles of microscopic size distributed in a liquid are known as "suspensions"; those consisting of two liquid phases are known as "emulsions."

The particles in solution, if sufficiently small, are in constant motion oscillating round a central position, and also undergoing an irregular translatory motion. Svedberg showed that the amplitude of the motion of a particle is directly proportional to the period, and inversely proportional to the viscosity of the liquid. Perrin showed that this Brownian movement conformed to the principles of the kinetic theory, and that the particles could be treated as large molecules. The stability of the solution is intimately connected with the electric charge. The charge can be altered by the addition of electrolytes, and may fall to zero with suitable concentrations, in which last case the solutions precipitate. It has long been known that the speed of settling of such suspensions can be increased by the addition of electrolytes. In systems of two liquid phases it can be shown that very small liquid particles, approaching ultramicroscopic dimensions, possess a high degree of rigidity. Systems of two liquid phases possessing few and widely separated particles, differ in no important respect from systems containing rigid particles; but an important difference appears as the amount of disperse phase per unit volume increases. In the case of rigid spherical particles in contact, the disperse phase may reach a maximum of 74 per cent. of the total volume. If the disperse phase be liquid, the globules may not merely touch one another but become flattened at the points of contact, from which circumstance it is obvious that there is no limit to the ratio

$$\frac{\text{volume of disperse phase}}{\text{total volume}},$$

which ratio may approach unity.

The distinguishing feature of colloids is their enormous surface development. A variety of processes which affect surface energy occur at boundary surfaces between two phases, such as compressibility, change of solubility, electrical charge, etc.

When solids are immersed in fluids, the film at the interface behaves as if stretched; all free surfaces of liquids exhibit this property. Now if colloidal particles be suspended in a liquid containing in solution any substance which lowers the surface tension of the liquid it is clear that if this substance accumulates at interface of particle and liquid, the surface tension at this interface will be lowered. It has been concluded, from principles of thermodynamics, that increase of concentration at a surface will always occur when the potential of any form of energy at this surface can be lowered by the process. Such lowering may be thermal, chemical, electrical, mechanical (surface tension). This concentration at a surface is known as "adsorption."

Colloids take up by adsorption various other bodies, especially colloids, and the process is intensified if the interacting bodies have opposite electrical charges, lessened if similar charges.

The laws of formation of adsorption compounds are illustrated by reference to such phenomena as the following: (1) Physical partition in proportion to relative solubility as exemplified in the oft-quoted case of picric acid in water and ether. Picric acid is soluble in each of these liquids, but more soluble in ether than in water. Where constant quantities of picric acid, ether, and water are used a constant quantity of the picric acid, say four-fifths, is found in the ether, and the remainder, one-fifth, in the water. Double the picric acid, preserving the proportion of solvents as before, and the result is a solution of double the quantity of the acid in each of the solvents. (2) Strict chemical reaction as seen in the case of chlorine precipitated by silver. If to a solution of hydrochloric acid a solution of silver nitrate be added, sufficient to fix the whole of the chlorine, the whole of the chlorine falls, and the addition of further silver nitrate is without effect on the chlorine. (3) Adsorption between colloids. This is illustrated by the common case of filter paper

and various dyes. If filter paper be immersed in a dilute solution of dye, a portion of the latter adheres to the paper, but not the whole: here is a precipitate (chemical) and at the same time a partition of the dye (physical). Double the concentration of the dye and, unlike the chemical reaction, more dye is precipitated on the paper, and, unlike the physical, the quantity of dye adsorbed is not double but less; instead of two the factor is some root of two—mostly less than the square root. In other words, when the concentration is doubled the amount adsorbed is $2^{\frac{1}{n}}$, where n is greater than 1 and less than 2. Adsorption may be applied to any values of n less than infinity when it becomes purely chemical. When $n = 1$, physical partition is expressed. It is here to be noted that relatively more adsorption takes place in more dilute solutions.

Electrically-charged colloids and electrolytes can precipitate colloids carrying charges of the opposite sign. Organic colloids can be made positive or negative by addition of acid or alkali respectively. All these colloidal reactions appear to possess a physical and chemical aspect, in some cases one predominating, in other cases the other. Many reactions are obviously purely chemical. But certain colloids possess adsorptive affinities other than chemical, and this applies for the most part to enzymes.

Enzymes, as a rule, are destroyed by temperatures below 100° C. But some enzymes can withstand the temperature of boiling water. Heat is not, therefore, a test of enzymes. The catalytic properties are, in the end, the only certain means of identifying enzymes.

The form in which the substrate is presented to the enzyme is of considerable importance. This is illustrated by the following *in vitro* digestion which I carried out some time ago. In milk dried by the Merrill Soule process, the particles of caseinogen in the reconstituted fluid differ in character from those in raw milk. Adsorption between enzyme and substrate appears in this instance to be more complete in the dried variety; at any rate, digestion proceeds more rapidly.

Peptic Digestion.—Five grammes of powdered milk were rubbed up with 42·5 c.c. water and placed in a digesting jar. In a similar jar were placed 47·5 grammes fresh milk containing 3·4 per cent. of fat. To the contents of each jar were added 0·1 gramme HCl and 0·05 gramme pepsin in dry powder. The jars were placed in a 37° C. incubator for periods of two and four hours. The contents at the termination of these periods were thrown on fine hard and weighed filters, and the residues carefully dried on the filters at a temperature below the melting-point of butter fat. A series of five digestions gave a mean excess in the weight of the dry residue (proteins and fat) on the raw milk filter over that on the powdered milk filter of 0·095 gramme. On extracting the residues on the filters with ether, and drying the protein residues, the weight of the latter derived from raw milk was still greater than that from the powdered milk. The excess of protein residue in the raw milk sample was further greater by 0·05 gramme in the case of the two hours digestion than in that of the four hours digestion. The ethereal extract when dried (fat) was greater in the case of raw milk than in that of the powdered.

Action of Rennin on the above Solutions.—To 100 c.c. of each of the solutions 1·5 gramme of an active preparation of rennin were added and the mixtures set aside at 26° C. In thirty minutes a firm clot had formed in the raw milk solution, whereas in the solution of powdered material no clot appeared, but instead a granular precipitate. At the end of an hour the raw milk clot was quite dense, whilst no clot existed in the solution of powder.

Tryptic Digestion.—To the same quantities of raw milk and solution of powder as used in the peptic digestion were added 0·1 gramme Na_2CO_3 and 0·05 gramme powdered trypsin, and digestions were carried out at 37° C. for two, four, and eighteen hours. In a series of thirty digestions the protein residues were all greater in the case of fresh milk than in that of the powder. These differences ranged from 0·05 gramme to 0·4 gramme, with a mean of 0·148 gramme in the four hours digestions. As in the peptic digestions the ethereal extract of the residues when evaporated left a larger amount of fat in the case of raw milk and more proportionately than in the peptic digestions.

The fat in the powder solution is no longer in emulsion, but is in a granular condition. The rate of protein hydrolysis, both peptic and tryptic, is greater in the solution of powder than in the natural variety of milk.

The mechanical and other physical conditions pervading the mixture of enzyme and substrate are, in certain cases, factors of the first magnitude in enzymic hydrolysis, and are doubtless important also in those activities which result in oxidation and reduction. The following piece of work, which I executed in 1911, on the hydrolysis of castor oil, illustrates the first

portion of this statement. I quote the account of the work as it then stood:—

"In 1902 Connstein, Hoyer and Wartenberg described a series of experiments carried out at Charlottenburg, by which it was sought to determine the *modus operandi* of fat-splitting in vegetable oils by an emulsion of the castor bean. Hoyer continued the work in 1904 and made an attempt to isolate the enzyme. He used as activators of his enzyme acetic acid and sulphate of manganese.

"In 1906 Nicloux, after several years' work on the fat splitting properties of the castor-oil bean, commenced some years before that of the three authors mentioned, came to the conclusion that the cytoplasm of the seed contains the active agent, and that this substance acts in every way as an enzyme, but is not an enzyme.

"It is customary to-day to assume that hydrolysis is preceded by a combination of the hydrolyte with the enzyme—Emil Fischer's lock and key relationship between bodies of asymmetric configuration.

"It is known that esters of the lower terms are more difficult to hydrolyse than those of the higher; in other words those esters most readily soluble in water are most difficult of hydrolysis. Is this due to a previous hydrolysis of some portion of the hydrolyte, or to a previous hydrolysis of some portion of the so-called enzyme?

"In reviewing the experiments of Nicloux and Hoyer I worked with the castor-oil bean acting on its own oil and on cottonseed oil. The results were equally good in the two cases, so that no specificity can be claimed for the enzyme of the castor seed towards its own oil.

"I prepared an emulsion of ground castor beans and incubated it at 25° C. until hydrolysis of the oil had been definitely established. A measured quantity of the incubated emulsion was then added to a mixture of measured quantities of oil (castor or cotton, as the case might be) and water. The mixture was shaken for a few minutes at intervals of a quarter of an hour for some hours and then left. The percentage of free fatty acids formed in three days at laboratory temperature ranged from 80 to 85.

"On repeating Hoyer's experiments, in which he used acetic acid and manganese sulphate, I did not find that the addition of these bodies produced any increase in the amount of free fatty acids liberated.

"I noticed early in the experiments that if hydrolysis (fatty acid liberation) were not properly established in the emulsion (enzyme) the yield of free fatty acid was correspondingly low. Success in the experiment largely depends on the intimate mixture of oil and enzyme. The preparation of the enzyme demands the use of a quantity of water from which the enzyme can later be separated. This water when applied to oil is wholly inactive. Further, the active enzyme, when mixed with two or three volumes of water, alcohol, or acetone, rapidly loses its activity; whereas when mixed with two or three volumes of ether or benzene no loss of activity occurs. On the lock and key hypothesis the meaning of these contrasts is difficult to seek.

"Nicloux described his enzyme as refractory to heat when protected by oil; my emulsion, when heated to 60° C., rapidly loses its activity. But when the bean from which the emulsion is prepared is heated to 100° C. for twenty-four hours in a dry bath little or none of its activity is lost.

"Pancreatic lipase has been separated into two portions by ordinary filtration, and it has been found that the activity of the filtrate is not diminished by boiling, whereas heating the residue destroys its potential energy. I have not been able to effect any such separation in the castor bean enzyme.

"That the activity is related to nitrogen-containing matter can be demonstrated; but whether the nitrogen is active or not it is impossible to say. The total organic nitrogen of my active emulsions, as estimated by Kjeldahl's method, always amounted to at least 0·2 per cent.

"Cotton oil and castor oil, when carefully neutralised and freed from proteins, fails to undergo hydrolysis. If to this oil an enzymic emulsion, in which hydrolysis of fat has not yet commenced, be added, nothing results. But let hydrolysis be established in the emulsion, and hydrolysis proceeds in the added oil, irrespective of whether this oil be neutral or contain within wide limits (25 per cent.) free fatty acids.

"Perhaps the most striking of all these features is the failure of the prolonged heating at 100° C.—a temperature which kills practically all proteins—to interfere with the activities of the bean. Is it that in the case of the dry bean, when heated, hydrolysis fails to commence, whereas in the mixture of enzymes and water hydrolysis rapidly exhausts itself?"

Since this was written I have not met with any experimental work which has thrown light on the problems raised. Although fats are simple chemical compounds compared with proteins, and simple also compared with some carbohydrates, there are many problems connected with their metabolism of which we know nothing accurately.

Since Croft Hill, in 1898, showed for the first time, through the action of maltase on glucose, that a hydrolytic enzyme under certain conditions can become a synthetic enzyme, the impression has been steadily growing that the action of all enzymes is reversible, given the necessary conditions. Enzymic activity takes place in systems of at least two components; the enzyme phase contains less water than the solution of substrate; accordingly, if the substances to be synthesised are more soluble in the enzyme phase than in water, partition will favour greater concentration in this phase than in water, and the enzyme phase being poor in water synthesis will be still the more accelerated.

The conditions may be such that only a very small proportion of synthesis is effected, but this small amount of substance, as in the case of the synthesis of starch, may be precipitated in an insoluble form and thrown out of action as quickly as it is produced, so that in time a large accumulation may appear. Hill regards the storage of starch in plants and glycogen in animals as produced in this manner.

Pancreatic lipase hydrolyses fats and also synthesises them. Ethyl butyrate is readily formed from ethyl alcohol and butyric acid. Monobutyrin, a butyric ester of glycerol, and mono- and tri-olein have been prepared.

The value of this reversibility of the action of lipase is obvious in connection with the digestion and absorption of fat in the cells of the intestine; here the fat as it is synthesised is thrown out of the reacting system on account of its insolubility, and passed over to the side of the tissues.

It is probable that carbohydrates and proteins are synthesised by the enzymes that hydrolyse them and from the self-same products of hydrolysis.

Whether adsorption or the union between enzyme and substrate is always specific we do not know. In some cases the evidence is satisfactory that such specificity exists; in other cases not.

During the absorption of oxygen by plants various substances are produced which can effect oxidations not brought about by oxygen alone, such as the bluing of guaiacum and the conversion of hydroquinone into quinone. These substances are characterised by great instability. They are destroyed by heat, mineral acids, and various poisons. It is claimed that they act catalytically, and are of the nature of enzymes. Bertrand has given them the name "oxidase"; and Bourquelot has classed them with ferments because of the following characteristics common to enzymes: power to effect the transformation of an indefinite amount of material by means of an infinitesimal quantity of ferment; powers of oxidation subject to influence of temperature, increasing with a rise of temperature to 42°–45°, falling off with a further rise to 60°–70°, and being destroyed at 100°; insolubility in alcohol; solubility in water even after desiccation and precipitation by alcohol; adsorption by precipitates after the manner of colloids.

That H_2O_2 is formed during the oxidation of oxidisable substances was known to Schoenbein; and many observations on the production of H_2O_2 as the result of oxidation by molecular oxygen in the presence of water were made by Traube. This observer held that in autoxidation the oxygen molecule as a whole combines with the oxidisable substance or with the hydrogen of water under the influence of the oxidisable substance to form a peroxide—thus, when hydrogen burns in the air, H_2O_2 is the primary product of oxidation—and that the resulting water is due to the reduction of the peroxide by hydrogen—

$$H_2 + O_2 = H_2O_2$$
$$H_2O_2 + H_2 = 2H_2O.$$

He held that water actively participates in all autoxidations, and that it is necessary even in such cases as the oxidation of carbonic oxide—

$$CO + \begin{matrix} HO\ H \\ HO\ H \end{matrix} + O_2 = H_2CO_3 + H_2O_2$$
$$CO + H_2O_2 = H_2CO_3$$
$$2H_2CO_3 \quad = 2CO_2 + 2H_2O.$$

Traube explained the carrying of oxygen as due to the oxidation of the second oxidisable substance by the H_2O_2 resulting from the oxidation of the carrier in the presence of H_2O. He held, contrary to the views of Hoppe-Seyler, that it is not the oxygen molecule that is decomposed in autoxidations, but the molecule of H_2O with liberation of atomic hydrogen, which last combines with molecular oxygen to form H_2O_2.

That the (OH) group of water plays many an important part in animal catabolism there can be no doubt. Even oxidation of saturated compounds in the laboratory consists for the most part in the replacement of H by OH. In the case of the hydrocarbon CH_4, Bone has shown that in both slow and explosive combustion hydroxylated molecules appear prior to the final products of combustion. He has identified formaldehyde and steam. He holds that formaldehyde at high temperature splits into carbonic oxide and hydrogen, which ultimately become CO_2 and H_2O—

$$CH_4 \rightarrow CH_3.OH \rightarrow CH_2(OH)_2 \rightarrow COH_2$$
$$\rightarrow CO + H_2 \rightarrow H_2O + CO_2.$$

Many biochemical oxidations involving the formation of similar hydroxylated intermediate compounds occur.

Those compounds which are catabolised in the body, viz., proteins, carbohydrates and fats, are quite resistant to the action of oxygen under ordinary conditions. In the presence of oxidases their carbon passes easily into CO_2. It was thought at first that H_2O_2 was the essential oxidase, but later it was recognised that a large number of peroxides might occur as intermediate stages in autoxidation. Indigo alone is unaffected by oxygen. Associated with benzaldehyde one half of the oxygen secured

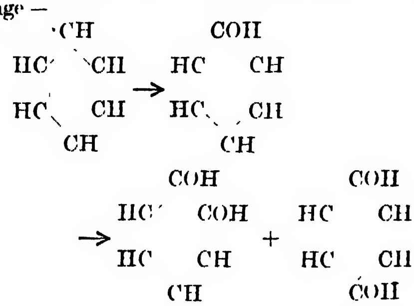
for the autoxidation of the aldehyde is used in oxidising the indigo. Villiger and Bayer have demonstrated the mechanism of this reaction: Benzaldehyde unites with O to form benzoyl-hydrogen peroxide, $C_6H_5.CO.O.OH$. In the absence of other oxidisable material this body interacts with a second molecule of benzaldehyde to form two molecules of benzoic acid—

$$C_6H_5.CO.O.OH + C_6H_5.COH = 2C_6H_5.COOH.$$

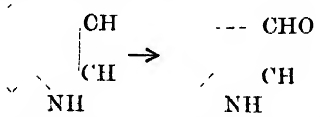
In the presence of indigo only one molecule of benzoic acid is formed, whilst the indigo is oxidised.

As Dakin points out, if the hypothesis of superoxide be correct, one would expect a certain similarity between the oxidations effected in the body and those brought about by the simplest peroxide, viz., H_2O_2; and such similarity exists.

Benzene is oxidised in the body to phenol, catechol and quinol. H_2O_2 produces the same change—



Indol is oxidised in the body to indoxyl. H_2O_2 produces the same change—



Grape sugar may be oxidised to glycuronic acid. H_2O_2, and H_2O_2 only, produces the same change *in vitro*—

$$\begin{array}{lcl} CH_2OH & & COOH \\ | & & | \\ (CHOH)_4 & \rightarrow & (CHOH)_4 \\ | & & | \\ COH & & COH \end{array}$$

As shown by Knoop, saturated fatty acids in the body undergo oxidation in the β position, *e.g.*, butyric acid yields acetoacetic acid. H_2O_2 alone produces the same result *in vitro*—

$$\begin{array}{lcl} CH_3 & & CH_3 \\ | & & | \\ CH_2 & \rightarrow & CO \\ | & & | \\ CH_2 & & CH_2 \\ | & & | \\ COOH & & COOH \end{array}$$

Hydroxy acids are oxidised to ketonic acids in the body and by H_2O_2—

$$\begin{array}{lcl} CH_3 & & CH_3 \\ | & & | \\ CHOH & & CO \\ | & & | \\ CH_2 & \rightarrow & CH_2 \\ | & & | \\ COOH & & COOH \\ \beta\text{-hydroxy butyric} & & \text{aceto-acetic acid} \end{array}$$

Amino- acids and ketonic acids are oxidi to lower fatty acids with separation of CO_2 a NH_3 or H_2O. Glycerol may be oxidised by body and H_2O_2 into glyceric aldehyde—

$$\begin{array}{lcl} CH_2OH & & CH_2OH \\ | & & | \\ CHOH & \rightarrow & CHOH \\ & & | \\ CH_2OH & & COH \end{array}$$

A host of other biochemical reactions, such as the oxidation of acids, aldehydes, and alcohols, may be effected in the test tube by H_2O_2.

Reference must be made to the saturated and unsaturated acids. In the body these two types appear to be oxidised equally easily. *In vitro* the saturated acids are infinitely more difficult of oxidation than the unsaturated. Again, the facility with which H_2O_2 performs the oxidation approximates that of the body. On the other hand, oxalic acid, whilst readily oxidised *in vitro*, is most difficult of oxidation in the body. In like manner it is scarcely attacked by H_2O_2.

Notwithstanding the analogies quoted, as above mentioned, H_2O_2 is not the peroxide present in living cells. Any such conception is at once put out of court by the fact that the widely distributed enzyme catalase at once decomposes it.

The path of oxidation is not always continuous; reductions not infrequently occur. And considering the manner of enzymic action, especially the property of reversibility, such activities are to be expected. A striking example of reduction, coupled with oxidation, is exemplified in the so-called reaction of Cannizzaro. When aldehydes are treated with alkalies two molecules of aldehyde undergo transformation in such a manner that one is reduced to the corresponding alcohol, whilst the other passes over into the acid—

$$2R.COH + H_2O = R.CH_2OH + R.COOH.$$

Parnas and Battelli and Stern showed that this reaction takes place in the tissues.

These processes of oxidation that are constantly taking place in all living tissues are even more important than those of hydrolysis,

inasmuch as through them heat and other forms of energy are produced.

Schmiedeberg, and after him Abelous, perfused fresh liver tissue with oxygenated blood containing salicylaldehyde and recovered salicylic acid. The solubility of this aldehydase was studied by Jacoby, who found that 60 per cent. saturation $(NH_4)_2SO_4$ threw down the enzyme. He dissolved it in water, reprecipitated it with alcohol, and found that on again dissolving it, no reduction had occurred in its oxidising properties.

Laccase, tyrosinase, oenoxidase, maloxidase, olease, purpurase, and other oxidases have been carefully studied by a number of able observers.

Tyrosinase, whilst not so widely distributed in nature perhaps as laccase, has been found in a large number of plants and animals, also in bacteria. Gessard found that the melanotic pigment in certain tumours of the horse was produced in the same way as the ink of the cuttle-fish, viz., by the interaction of a chromogen and an oxidising ferment. He was able to obtain tyrosine from such tumours, with which he produced the colour changes characteristic of tyrosinase. He concluded that tyrosine is the chromogen whose oxidation by tyrosinase gives rise to the pigment in melanotic tumours. Gessard believes that the same reaction causes the colour of the negro, the ink of the cuttle-fish, and the black pigment of mushrooms.

Bertrand has studied the action of tyrosinase on various bodies analogous in structure to tyrosine. He observed no colouration with glycocoll, alanine, phenylacetic acid, phenylpropionic acid, phenylamino acetic acid, phenylmethylamine, and phenylalanine. With compounds containing phenolic hydroxyl characteristic colours were observed. He concludes that only substances containing phenolic hydroxyl are oxidised by tyrosinase.

Tyrosinase contained in the skins of animals only acts on tyrosine in the presence of small amounts of iron.

It may be incidentally noted here that I have found in the fæces of individuals exhibiting melanotic pigment abnormally large quantities of tyrosine or other hydroxy-phenyl amino-acid.

Another class of enzymes concerned in the oxidations continuously occurring in plants and animals is that of the peroxidases. Bourquelot named them the indirect oxidising ferments. Bach and Chodat regard their action as specific in that in the absence of H_2O_2 or similar peroxide they have no oxidising power. They find that they not only activate hydrogen peroxide and the peroxides resulting from the slow oxidation of such bodies as alcohol, ether, and the essential oils, but also that they increase the oxidising powers of the oxidases.

The catalases are the most widely distributed of all the oxidising enzymes, for every tissue which gives the peroxide reaction with guaiacum and H_2O_2 can also decompose the peroxide, whilst certain tissues able to effect the latter reaction cannot effect the former. Their action is also regarded as specific. They all possess the common property of being able to decompose H_2O_2 into water and molecular oxygen, and the negative property of being unable to activate the oxygen of the peroxide toward oxidisable substances.

When it became known that different proteins, fats, and carbohydrates are not physiologically equivalent—that certain chemical groups execute special functions in the animal organism —it was seen that progress could not be made apart from the study of such groups as were met with in the intermediate products of metabolism. The study of intermediate products in the oxidation of fatty acids has led to much valuable information in this direction. The most easily digested of all fats are the fats of milk. They are composed of fatty acids containing 4, 6, 8, 10, 12, 14, 16, and 18 carbon atoms. They all undergo complete oxidation in the body with formation of CO_2 and H_2O. The 4-carbon acid (butyric) is the lowest that occurs in the body in the form of fat. Propionic, acetic, and formic acids occur in the organism, but not in the form of fat. Fats of 16 and 18 carbon atoms predominate. The oxidation of a molecule of palmitin, stearin, or olein necessitates the formation of various intermediate bodies. The ease with which such intermediate substances undergo oxidation led to the introduction of a refractory radical, phenyl, by Knoop. This observer worked with the phenyl derivatives of acetic and the next three acids. He found that phenylacetic acid is not oxidised in the animal body, but combines with glycocoll to form phenaceturic acid. On the other hand, β-phenyl propionic is oxidised to benzoic, which unites with glycocoll and passes out of the organism as hippuric acid. On considering these two reactions Knoop concluded that the oxidation of the 3-carbon atom side-chain of phenyl propionic acid did not occur with formation of a 2-carbon side chain—phenyl acetic otherwise phenaceturic acid would have appeared, as above. Two-carbon atoms appeared to have been removed at once. Further work by Knoop and confirmatory work by Dakin proved this to be true.

On his experiments Knoop conceived his hypothesis of β-oxidation, viz., that the H attached to the β-carbon atom is attacked for oxidation, and that consequently the carbon chains are reduced by the loss of two or a multiple of two carbon atoms at a time. It seemed likely that β-hydroxybutyric acid and acetoacetic acid excreted by diabetics were intermediate products of the β-oxidation of butyric or higher fatty acids. Experimental work on dogs proved that an increased excretion of β-hydroxybutyric acid and acetoacetic acid followed administration of salts of butyric acid-

$$CH_3.CH_2.CH_2.COOH \rightarrow CH_3.CHOH.CH_2.COOH \rightarrow CH_3.CO.CH_2.COOH.$$

Knoop's theory met with much opposition on the ground that such oxidation in the β position was unknown in pure chemistry. Dakin showed that such a reaction *in vitro* was not only possible, but he produced it. He neutralised butyric acid and digested it at 37° with H_2O_2. He obtained acetoacetic acid, acetone, lower fatty acids and CO_2. When he increased the temperature the acetoacetic acid was converted into acetone with loss of CO_2, according to the general reaction of β-ketonic acids. It was not possible to detect β-hydroxybutyric acid.

The reaction was extended to higher fatty acids, which all gave the corresponding ketone containing one less carbon atom. Later Embden showed that acetone was derived from acetoacetic acid, and that in the normal fatty acid series from propionic to decoic acetoacetic acid formation only occurred in those acids possessing an even number of carbon atoms. Although β-hydroxybutyric acid could not be detected it is not likely that a single reaction could shorten the carbon chain by two atoms. Embden showed that both butyric and β-hydroxybutyric acids when perfused through a surviving liver gave origin to acetoacetic acid.

Of acids with branched chains the oxidation of three containing the isopropyl group—

$$\begin{matrix} CH_3 \\ CH_3 \end{matrix} \rangle CH—$$

viz., isobutyric, isovaleric and isocaproic, have been carefully studied, with the result that it is found that they tend to part with their side chains and then undergo oxidation on similar lines to those of the straight-chain acids.

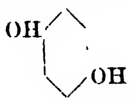
Embden, in studying the catabolism of amino-acids by his liver-perfusion method, found that the behaviour of these acids is similar to that of the derived fatty acid containing one less carbon atom. Leucine gives acetoacetic acid in the same manner as does isovaleric acid, so that it is reasonable to suppose that the second appears as an oxidation product of the first—

$$\begin{matrix} CH_3 \\ CH_3 \end{matrix} \rangle CH.CH_2CHNH_2.COOH + O_2 = \begin{matrix} CH_3 \\ CH_3 \end{matrix} \rangle CH.CH_2.COOH + NH_3 + CO_2.$$

Knoop has studied the catabolism of γ-phenyl α-aminobutyric acid and shown that α-ketonic acids form at once stages in the oxidation and synthesis of amino-acids.

Substances containing the benzene nucleus do not readily undergo oxidation in the animal organism. Exceptions to this rule are found in phenylalanine, tyrosine and tryptophane.

Considerable attention has been paid to the condition known as alcaptonuria, in which the body fails to oxidise phenylalanine and tyrosine, converting them into homogentisic acid—



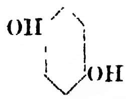
$CH_2.COOH$ (1.4 dioxybenzene acetic acid)

which appears in the urine. This body has been definitely proved to be derived from phenylalanine and tyrosine.

The relationship of the three bodies is seen in their structural formulæ—

$CH_2.CHNH_2.COOH$, phenylalanine.

$CH_2.CHNH_2.COOH$, tyrosine.



$CH_2.COOH$, homogentisic acid.

It was assumed that homogentisic acid was a normal intermediate product of the oxidation of phenylalanine and tyrosine and that the alcaptonuric failed finally to oxidise it through acetoacetic acid to CO_2 and H_2O.

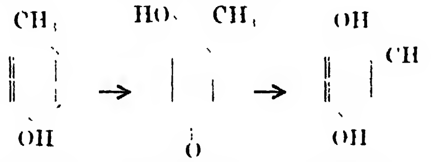
To this view Dakin objects, relying on the analogy from experiments by Neubauer and Knoop on the oxidation of phenyl derivatives of α-aminoacetic and α-aminobutyric acids in which α-ketonic acids are first produced.

The corresponding α-ketonic acids derivable from phenylalanine and tyrosine are $C_6H_5.CH_2.$

CO.COOH (phenylpyruvic acid) and $C_6H_4OH.CH_2.CO.COOH$ (*p*-hydroxyphenylpyruvic acid). Both of these acids are easily oxidised in the body with breaking up of the benzene nucleus; both produce homogentisic acid when administered to an alcaptonuric patient; and both readily yield acetoacetic acid when perfused through a surviving liver. So far they resemble phenylalanine and tyrosine, from which they may be derived. Moreover, Embden has demonstrated the synthesis of the amino- acids from these ketonic acids. With regard to the next step, Dakin does not believe that the ketonic acids are oxidised to saturated acids with one carbon atom less because the phenylacetic acid and *p*-hydroxyphenylacetic acid which would be formed both resist further oxidation in the body. These do not yield homogentisic acid when administered to an alcaptonuric patient, nor acetoacetic acid when perfused through a surviving liver, but when fed to animals are secreted unoxidised in conjunction with glycocoll.

It appears, then, that the next step involves the opening of the benzene ring, and Dakin quotes the analogy of Jaffe's observation, viz., that muconic acid may be isolated from the urine of dogs fed on benzene. Dakin and Wakeman think that the molecule of acetoacetic acid is formed at the expense of two carbon atoms of the nucleus and two of the side chain.

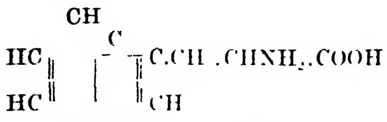
From the fact that homogentisic acid has its two OH groups on either side of the position of the OH in tyrosine it seems necessary to assume that the hydroxylation of the nucleus is effected by some molecular rearrangement involving a change in the relative positions of the OH group and side chain in tyrosine, and Dakin finds analogies for this kind of change in the rearrangement within the molecule of *p*-cresol undergoing oxidation to methylhydroquinone—



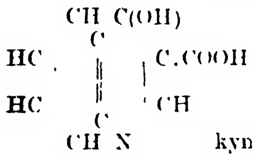
p-cresol tolu-quinol methyl-hydroquinone.

The oxidation of tryptophane, indole *a*-aminopropionic acid, in the normal human organism is apparently complete. Ellinger fed tryptophane to dogs, and found an increase of kynurenic acid in the urine. He was able to produce the same substance in rabbits. The conversion of tryptophane into kynurenic acid requires the entrance of an additional carbon atom into the indole ring with formation of a quinoline nucleus. This type of reaction has been accomplished *in vitro*. Ellinger obtained *β*-chlorquinoline and indole aldehyde by acting on indole with potash and chloroform.

The oxidation proceeds most likely by the formation of indylpyruvic acid as a first step, the opening of the pyrrole ring and the formation of the quinoline nucleus by incorporation of the *β*-carbon atom of the side chain and oxidation of the CO.COOH to COOH—



tryptophane.



kynurenic acid.

—C C.CH₂CHNH₂ COOH —C ⟶ —C.CO.CH₂ CO COOH	Analogy of conversion of side chain of phenylalanine into phenylpyruvic acid.

With the possible exception of pentoses the carbohydrates of the foodstuffs yield glucose in digestion, and as glucose are assimilated and catabolised. Glucose is for the most part stored as glycogen in the liver and muscles, but on utilisation is once more changed into glucose. The oxidation of carbohydrates is then the oxidation of glucose. Schmiedeberg and others long since showed that when camphor was injected into the body it was excreted in the urine in combination with glycuronic acid. Paul Mayer showed that rabbits starved until their store of glycogen was nearly all used, produced little or no glycuronic acid on administration of camphor; but on subcutaneous injection of camphor and glucose the excretion of glycuronic acid appeared as usual. Jolles has oxidised glucose in neutral solution with dilute H_2O_2, so as to obtain glycuronic acid. Bromine water readily oxidises glycuronic acid to saccharic acid, and this in turn is readily oxidised to tartaric and oxalic acids.

That glycuronic acid is derived from glucose appears certain, but the catabolism of glucose through the form of saccharic acid is doubtful. It is known that lactic acid may give rise to glycogen, and when given to a diabetic animal to glucose. It is much more likely that lactic

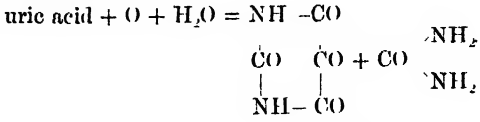
acid is an important stage in the oxidation of glucose. There is no evidence to show that saccharic acid has ever been found in any animal tissue or excretion.

Since Salomon discovered, thirty-five years ago, that purine bases are to be found in the nucleins which exist in the nuclei of cells, much work has been done to explain the chemistry of these nuclear constituents.

Nucleoprotein yields nuclein and protein. Nuclein yields nucleic acid and protein. Nucleic acid yields carbohydrates (pentoses, hexoses, etc.), phosphoric acid and bases.

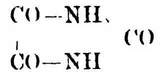
The four bodies, hypoxanthine, xanthine, adenine, and guanine, are known as the purine bases, and are closely related, chemically and biologically, to the important metabolic end-product uric acid. Emil Fischer's work threw much light on the whole group of purines and

nitric acid or chlorine, alloxan and urea are produced—



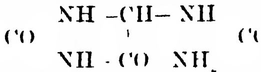
alloxan.

The oxidation of alloxan produces parabanic acid—

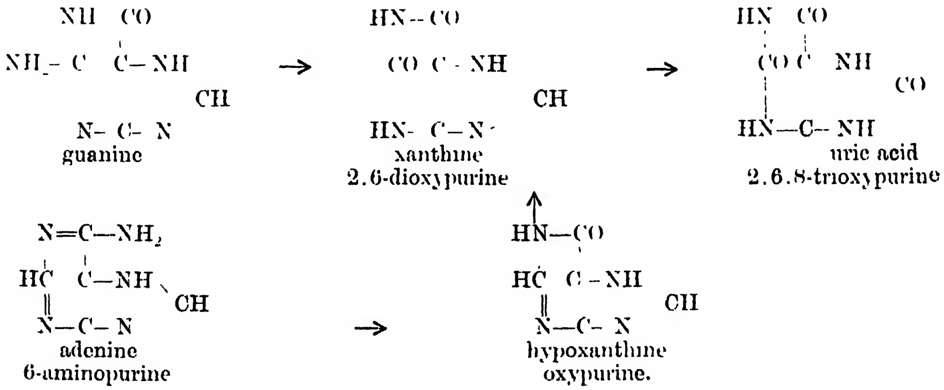


which decomposes in boiling water into urea and oxalic acid.

Uric acid can also be oxidised into allantoine—

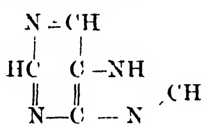


The relations of the purine bases to uric acid are seen in their structural formulæ—

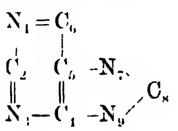


guanine; xanthine 2.6-dioxypurine; uric acid 2.6.8-trioxypurine; adenine 6-aminopurine; hypoxanthine oxypurine.

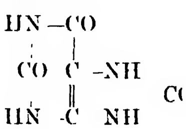
their derivatives. He obtained purine, a strong base readily soluble in water —



and numbered the ring thus—



Uric acid—



is 2.6.8-trioxypurine.

This formula is in conformity with definite reactions; uric acid, heated with HI and fuming HCl in a sealed tube, gives glycocoll, carbon dioxide and ammonia. Oxidised with

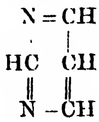
Three bodies closely related to the purines are

Caffeine 1.3.7-trimethyl - 2.6-dioxypurine;

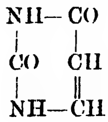
Theobromine 3.7-dimethyl - 2.6-dioxypurine:

And Theophylline 1.3-dimethyl 2.6-dioxy-purine.

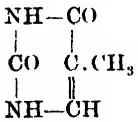
Three remaining bodies related to this group of cleavage products of nucleic acid have a pyrimidine ring instead of a purine ring —



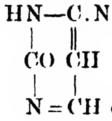
pyrimidine,



uracyl, 2.6-dioxypyrimidine,

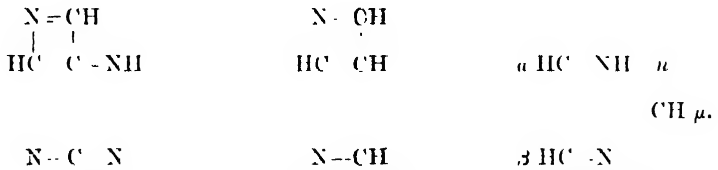


thymine, 5-methyl—2.6-dioxy-pyrimidine,



cytosine 6.amino - 2-oxypyrimidine.

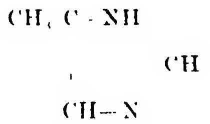
Burian tried to show how the purine bases are held in the nucleic acid molecules. He regarded them as primary cleavage products, as they were readily separated off by boiling water. The purines may be considered as a condensed nucleus formed of a pyrimidine and an imidazole ring—



purine pyrimidine imidazole

Several definite reactions support this view.

Knoop and Windaus have shown that if grape sugar be treated in the cold with ammoniacal zinc hydroxide an oxygen-free base, methyl imidazole—



is produced in quantity.

This is a most important link between the carbohydrates and the purine bases. It is possible that analogous reactions occur in plants. No evidence exists as yet to warrant the view that like changes take place in animal tissues.

Horbaczewski showed that the ingestion of nucleins increases uric acid in the urine, whilst food free from nuclein has no such effect. He also allowed spleen pulp, which contains no purine bases, to putrefy and separated xanthine and hypoxanthine. By shaking the putrefied pulp in air, he was able to obtain uric acid from oxidation of the bases.

Spitzer passed air through aqueous extracts of spleen tissue at 40°, excluding putrefaction, and obtained uric acid. He noticed that the quantity of purine bases decreased as the quantity of uric acid increased. Further purine bases added to the digest were converted into uric acid. He thus established the presence of the xanthine oxidases which convert purine bases into uric acid.

Schittenhelm found that in cattle the spleen, lungs, liver, intestine and kidney, can convert purine bases into uric acid in the presence of a constant supply of oxygen. He found that adenine was completely transformed thus—

adenine $\rightarrow$ hypoxanthine $\rightarrow$ xanthine $\rightarrow$ uric acid.

He further discovered that kidney, liver, and muscle extracts possess the power of destroying the newly-formed uric acid, and established the presence in the kidney of a uricolytic enzyme.

We may take it then that nucleic acid can be broken up by nuclease, an enzyme found in all tissues, that the purine bases are converted by enzymes into uric acid, and that uric acid can be destroyed by a third variety of enzyme.

Whilst purine bodies can be derived from ingested nucleins, this cannot be the only source, since purines are found in the urine during starvation and on a purine-free diet. A constant production of purine exists possibly through the destruction of cell nuclei. Uric acid and purines from this source are termed endogenous, in contradistinction to exogenous derived from nuclein-containing food. Burian and Schur determined that the endogenous uric acid elimination did not vary from day to day in the same individual, but was a constant factor of his metabolism.

A purine-free diet is found in such articles of food as milk, eggs, bread, potatoes, fats, and sugars, as none of these contain nucleins, and hence can form no exogenous purines. Burian found that on such a diet the uric acid elimination was quite independent of the quantity of protein ingested. Rockwood afterwards showed that the elimination of endogenous uric acid was independent of the calorific value of the diet. In Chittenden's experiments, spread over a period of a year and nine months, the low protein diet and moderate intake of food did not influence the output of uric acid.

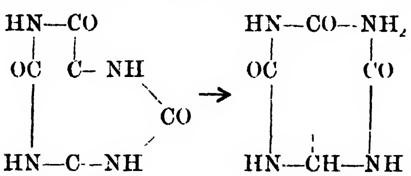
It is a remarkable fact that the liver has the power of oxidising uric acid, but not purine bases; hence the behaviour of exogenous purines must be the same as if they arose from the general metabolism.

Ingestion of the pyrimidine bases has failed to yield purines. It had been found that exercise

had no effect on the purine excretion in the urine of twenty-four hours in man. Burian finds, however, a large increase in the purine elimination for an hour or two after severe muscular exercise, and that this is followed by a compensatory reduction in the output during subsequent hours. He concludes that the most general source of endogenous purines is a constant production of hypoxanthine in muscle. Beebe has shown that endogenous purine metabolism is unchanged by the ingestion of alcohol, but that when alcohol was accompanied by nuclein-containing food the output of uric acid rose distinctly. In gout the oxygen absorption and carbondioxide elimination is the same as in health. Indeed, the general metabolism, exclusive of the purine factor, is the same as in health. In the light of modern research Garrod's view of gout, formulated about the middle of last century, appears as reasonable as any that has since been put forward, viz., that gout is due to an excess of urates in the blood. Minkowski regards gout as due to an abnormal metabolism in the nuclei of cells. But in leuchæmia, with a great increase in nuclei and large destruction of nucleoprotein with an enormous elimination of uric acid, there is no gout. Von Noorden suggests that gouty patients be tested for their tolerance for purines as diabetics are tested for their tolerance for carbohydrates.

The work recently accomplished by Burian, Shittenhelm, Wiechowski, and others, has demonstrated that the purine bases undergo oxidation by means of enzymes irregularly distributed in various animal species: they are chiefly found in glandular organs, especially the liver, spleen, and pancreas. It has been found possible to separate and, to some extent, purify these enzymes, and to study their action on various purine derivatives. The oxidation of hypoxanthine to xanthine and of xanthine to uric acid are ascribed to one enzyme—xanthine-oxidase.

The oxidation of uric acid to allantoine—

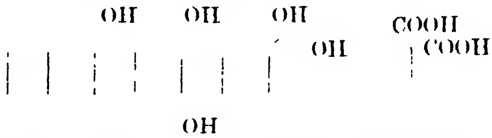


uric acid allantoine

is effected by uricase, an "uricolytic" enzyme. Nothing is known of the decomposition of allantoine by enzymes. According to Wiechowski allantoine is the normal end-product of purine metabolism in the carnivora.

Aromatic hydrocarbons undergo an oxidation with introduction of hydroxyl groups in the nucleus or oxidation of the side chain with formation of acids.

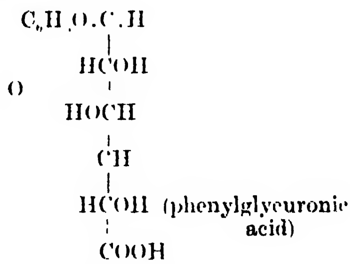
Jaffé fed dogs with benzene and found small quantities of muconic acid in the urine. On feeding muconic acid to rabbits he found that it was exceedingly easily oxidised. A certain amount of benzene probably undergoes complete oxidation in the body. The successive steps of such oxidation are not known, but the following have been suggested—



benzene phenol quinol catechol Muconic acid by rupture of the benzene ring.

Phenols formed thus are not excreted as such, but in combination with sulphuric acid and glycuronic acid.

Salkowski and Neuberg have determined the constitution of phenylsulphuric and phenylglycuronic acids: $C_6H_5O.SO_2.OH$ (phenylsulphuric acid)—



Ethylbenzene, propylbenzene, and toluene are oxidised to benzoic acid and excreted as hippuric without formation of phenols. This reaction may be imitated *in vitro* by the action of H_2O_2 and O_3.

But a remaining large number of aromatic compounds undergo substitution of H groups in the nucleus by OH groups. When benzene is ingested a part escapes unchanged by the lungs (Nencki and Sieber).

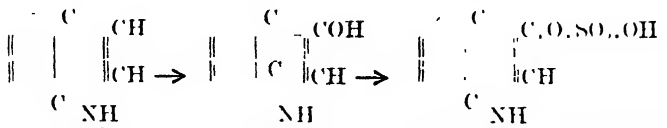
The bacterial decomposition of tyrosine in the intestine produces phenol and paracresol, which partly combine with sulphuric and glycuronic acids, and escape by the urine. A considerable portion of the phenol is oxidised to quinol and later to catechol, which are excreted as conjugation compounds with the above acids.

The three cresols are excreted in large measure with H_2SO_4.

No intermediate product of the oxidation of ethyl alcohol has been found in the body; it is probable that acetic acid is formed and subsequently completely oxidised.

The oxidation of aldehydes has been referred to in connection with mention of the Cannizzaro reaction. Nencki found indole amongst the products of the putrefactive decomposition of proteins by bacteria in the intestine.

Jaffé showed that this was the body from which urinary indican was formed. Brieger isolated the potassium salt of indican, and showed that acids hydrolysed it to indoxyl and sulphuric acid. Indican is known as indoxyl-sulphuric acid. A more correct designation is indyl-hydrogen-sulphate.



indole indoxyl indyl-hydrogen-sulphate

TANNING INDUSTRY OF THE PHILIPPINES.

An effort is being made to stimulate and develop the leather industry in the Philippine Islands. It is estimated that the producers and tanners of hides could save £70,000 annually by investing but little more capital than is now employed, simply by adopting modern methods. It is estimated that about 18,000 skins are tanned annually in the islands. The leather produced is manufactured into slippers and shoes of the lower grades. The value put upon this annual output of the tanneries is about £30,000. There are many skins—from deer, wild hogs, etc.—of which no use whatever is made.

The 125 tanneries are scattered through various provinces. Those of most importance are in Manila, Iloilo, Bulacan, Ilocos Norte and Ilocos Sur. The tanning is poorly done and from poorly selected skins. As a result, thick skins for making hard, thick sole leather come from the tanner flexible and incompletely tanned, through the use of weak tanning solutions and insufficient time in the tanks or vats. Not infrequently these leathers are not sufficiently tanned to prevent decomposition. At best such leathers are of light weight and porous and flexible.

The Bureau of Science recommends that four months be devoted to the tanning process. The process proposed is to immerse the skins first in a solution containing about one half per cent. of tannin and pass them gradually to baths of stronger solutions, the last solutions containing 10 to 15 per cent. of tannin. The present practice is generally to immerse the skins in a strong solution at first and allow them to remain only four or six weeks. The result is preserved skins rather than leather.

The Philippines are rich in tanning materials, which, properly employed, would make locally produced leather not only of the highest class, but also cheaper than that produced elsewhere. The mangroves, which abound in different parts of the islands, and the camanchile tree (*Pithecolobium dulce*),* which grows in great abundance in the Philippines, furnish a large percentage of tannin. The fresh bark of these contains often 15 to 25 per cent. tannin, but as a rule no more than 10 per cent. is utilised.

The cost of 100 kilogrammes (220·46 lb.) of camanchile bark is 24s.; about 10s. to 12s. of bark is needed to tan a hide that in finished form should be worth £3, but because of its poor quality the leather turned out is worth only about £2.

Investigation of the present system reveals great wastage. In one tannery 1,500,000 lb of bark was used, but it was found that only 40 per cent. of the tannin was utilised. Again, a poor quality of lime is used for depilation, and care is not exercised in the washing process. The tanned product is dried too rapidly; the thick skins are divided until they are fragile and more or less valueless.

According to a report by the correspondent at Manila of the Unites States Department of Commerce, the Government is endeavouring to reform the tanning methods, and also to create marketing facilities for handling all the available hides of the islands. A propaganda has been started by the Bureau of Science to induce small dealers in remote communities to purchase hides from producers with the assurance that they will find a ready market at Philippine tanneries. By teaching the tanneries the latest methods it is hoped to stimulate a keener interest in the industry and encourage them to expand.

An insignificant amount of hides has been exported during the last few years. In 1914, 23,486 lb. of carabao hides were exported to the British East Indies and Hong-Kong, and 101,435 lb., valued at £1,859, of hides of all other classes, principally to China and Hong-Kong, although small amounts were shipped to British East Indies, the United Kingdom, and the United States. This represents the high-water mark of hide exportation in the last few years.

* A Mexican tree, having edible pods and a bark rich in tannin; introduced from Mexico into the Philippines and Guam.

ENGINEERING NOTES.

Reduction Gear for Battleships.—The *Times* states that the adoption in America of this gear is of great importance; and second only in interest to the electric propulsion in the "California" is the use of mechanical reduction gear in the 31,000-ton battleships "Pennsylvania" and "Arizona," both of which are to be completed next year. These are quadruple-screw turbine vessels, the former being equipped with Curtis machine and the latter with the Parsons type. The two inner propellers are driven by the main high-pressure turbines, while each wing propeller shaft is coupled to main low-pressure ahead and astern turbines in the after engine-room, and to a high-pressure cruising turbine in the forward engine-room driving the shaft through a reduction gear. When the vessel is steaming under full power the cruising turbines are not in use, and the couplings between them and the low-pressure turbines are disconnected. Under cruising conditions the steam passes first into each cruising turbine, then through it the high-pressure turbine nearest it (which thus becomes an intermediate pressure turbine), and finally to the low-pressure turbine to which it is coupled. By this means it is thought that great economy will be effected, since the cruising turbines are designed specially as high-speed machines running at 2,500 revolutions per minute in the case of the "Arizona," and at 1,850 revolutions per minute in the "Pennsylvania," while the maximum speeds after reduction are 192 revolutions per minute and 120 revolutions per minute respectively. With this combination the efficiency of a high-speed turbine is gained with a low-speed propeller In the "Arizona" the power of the cruising turbine is 2,000 h.p, and in the "Pennsylvania" 1,600 h.p. The gears have been built by the Westinghouse Company, and the weight of each is in the neighbourhood of ten tons. They are provided with floating frames, which it is claimed render the pressure uniform on all the teeth under all conditions of load.

A High-speed Electric Railway.—A 2,400-volt third-rail electric railway—the first ever built to use such a high voltage with the third rail has just been completed in Southern Michigan. The line is owned by the Commonwealth Power Railway and Light Company of Grand Rapids, and has just been turned over to the Michigan Railway, the operating company. It consists of a new line, fifty miles long, from Kalamazoo to Grand Rapids, and branches to Battle Creek and Allegan, obtained by buying and electrifying a forty-four and a half mile branch of the Michigan Central Railroad connecting these two points. The Kalamazoo and Grand Rapids section represents the latest type of electric-railway construction, being designed for heavy loads and speeds up to ninety miles per hour. Except in the streets of Kalamazoo, and of a section of private land in Grand Rapids, the maximum curvature is 3°, and the maximum grade 1 in 100. Along the main line the third rail is an 80-lb. low-carbon rail rolled specially for this road, and on industrial sidings and passing tracks a 52-lb. relayer is used instead

Aeroplane Construction in Australia As a direct result of the war a new industry seems likely to be started in Australia, namely, the manufacture of aeroplanes. Recently we learned from the *Ironmonger* that the Australian Minister for Defence had drawn the attention of engineering firms to the project, and asked such firms to submit tenders for building aviation motors in the Commonwealth. Engines have hitherto been imported, but such importation has ceased as a result of the war. The Defence Department has received many inquiries, and firms from all over the Commonwealth have announced their willingness to build the necessary engines. The engine required is of the Renault type. It is expected that some orders for specimen engines will shortly be given. Meanwhile a staff of mechanics at Point Cook is working at the construction of a biplane, and further machines will be built as soon as possible

Mining Difficulties in Lapland—To deal with an annual output of four million tons of iron ore at Kiruna, within the Arctic Circle, electric machinery is largely used. A mining expert describes the electric shovels for loading the ore into the trucks. The power is obtained from the Parjus Falls, and is conveyed on two lines at a tension of 70,000 volts to Kiruna, where it is stepped down to 110 volts for the shovel motors. The shovels are of a heavy and substantial type. As a protection against low temperatures, the power chamber at the Falls is underground, blasted out of the solid rock, its roof being 50 feet below the surface.

Aero Engineering.—An article in the *Engineering Record* of New York states that new branches of engineering which appear from time to time and are novelties for a while, almost without exception develop into important fields, in which specialists are trained, and which finally become closely identified with the necessities of civilisation. Such will undoubtedly be the case with aeronautics. It is interesting to note the variety of influences which are working to develop the art of flying to a point where it will be more useful than at present. The greatest of these, of course, is the need for aircraft in military operations, and no doubt much progress toward the production of safer and more effective machines will result from the urgent need in the present European conflict. Recently, on the occasion of an accident to a pleasure boat, just off shore from a popular beach resort in California, it was demonstrated that an aeroplane could be used effectively for dropping life-preservers to persons struggling in the water beyond the surf line. This incident started a campaign to have the life-saving service equipped with aeroplanes. The plan, if successful, would

greatly increase the effectiveness of that department in carrying aid to vessels in distress. Post-office officials in Washington have long recognised the advantage of using aero delivery service for crossing the deserts and mountains of the west and north, and in many cases where the means of communication are uncertain it seems almost a necessity. Even in well-settled districts mountain chains often necessitate circuitous rail routes, and these afford opportunity for great time-saving if aerial mail services were established For example, a letter leaving Portland, Oregon, on Monday, does not reach Eureka, California, *via* San Francisco, until Thursday, yet the stretch which causes the delay could be bridged by a two-hour aerial run between Eureka and Redding, California, which are only 95 miles apart as the crow flies. Those whose duty it is to watch for forest fires, to patrol transmission lines, or to carry relief into frozen wastes or the desert areas, and, in short, many whose work is now accomplished under difficulties because of transportation problems, will be able greatly to increase their range and efficiency when the aeroplane as a safe and well-controlled conveyance, is at their disposal.

Electric Railway Progress in England —The first section of the large mileage which the London and South Western Railway has converted from steam to electric traction will be opened shortly, and serves as a reminder of the important work in this field which is now being carried out by British railway companies. Both the London and South Western and London and North Western Railways are engaged in the equipment for electrical operation of an aggregate of some hundred miles of track, and, in spite of delay caused by the difficulty of obtaining the necessary supplies and the shortage of labour, even the stress of war conditions is only retarding and not stopping progress with the work The system which is being installed on the railways to which reference has been made is, with certain modifications, the same as that which has been long tested under service conditions on the London underground railways. Even the system adopted by the Brighton Company, although there is only one other example of it in Great Britain, cannot be regarded as a novelty, as the single-phase alternating current method of working has been largely employed on American and other foreign railways It has been left for the Lancashire and Yorkshire Railway to attempt something new, as far as the United Kingdom is concerned. After experience of the high-tension overhead direct current system which has been experimentally installed on the Bury-Holcombe Brook line, the section of railway between Manchester and Bury is being equipped with high-tension direct current on the third-rail system. It is satisfactory to learn that in some branches of electric railway work British engineers are keeping abreast of the times. The above particulars are from the *Times Engineering Supplement.*

NOTES ON BOOKS.

THE DEVELOPMENT AND PROPERTIES OF RAW COTTON. By W. Lawrence Balls, M.A. London A. & C. Black, Ltd. 5s. net.

The principal object of this work is to present the history of the development of cotton-lint. The author was formerly botanist to the Khedivial Agricultural Society of Cairo, and to the Egyptian Government Agricultural Department, and for some ten years he kept records of field crops in the form of plant-development curves The net result of his observation goes to prove that cotton is a law-abiding plant, and not the capricious crop that it has often been supposed to be.

Mr Balls begins with the development of the pedigree of the plant, and in this chapter he has some interesting views on the question of seed distribution by wind and the evolution of lint His second chapter deals with the development of the plant, including the effects of irrigation, sunshine, manure, quality of the soil, etc , the third and fourth with the development of the boll; the fifth with the development of commercial lint, and the sixth with the development of cotton-growing Two appendices are devoted to the methods of investigation and tables of statistical data

The book is of particular value because hitherto little accurate observation has been kept upon cotton, in spite of its enormous financial importance Though the author's experience was chiefly confined to Egypt, no doubt many of his conclusions will be applicable to the crops grown in other parts of the world The book is thoroughly complete and scientific in its treatment of the subject, and should prove valuable to all interested in the production of cotton

PHILLIPS' PAPER TRADE DIRECTORY OF THE WORLD, 1914 15 London: S. C. Phillips & Co. 15s. 6*d*.

An immense amount of information relating to the paper trade is contained in this volume, and its international character is shown by the fact that some of the articles are printed in seven languages, including Russian. In the case of enemy countries it has, of course, been impossible to obtain reliable information, but in all other cases no efforts have been spared to secure the most recent statistics.

The principal features of the book include lists of the paper mills of the world, with a classification of the various makes of paper, the wood-pulp mills of the world, buyers of paper, boards and stationery, and makers of millboards, leather boards, paper agents, export paper shippers, etc., together with much other information likely to be useful to those engaged in the paper trade.

A list of the paper mills in thirty-six countries of the world shows that the United States come first, with 1 012 mills, Germany second with 895; Italy third, with 426; Austria-Hungary fourth, with 417; France fifth, with 383; and Great Britain sixth, with 356.

GENERAL NOTES.

Agriculture in the United Kingdom.—A summary with comparisons for 1914, based upon the preliminary statements made in June last, has just been issued by the Board of Agriculture, showing the areas in the United Kingdom under crops and the number of live stock on agricultural holdings. The area for wheat was 2,334,090 acres, an increase of 429,160 acres on the year; barley covered 1,523,980 acres, a decrease of 347,190 acres; whilst the area under oats was 4,148,050 acres, an increase of 270,090 acres. Potatoes accounted for 1,202,520 acres, an increase of 5,510 acres, but in the cases of turnips and swedes, mangolds, clover, sainfoin, and permanent grass for hay there were decreases varying from 7·7 to 1·1 per cent. Under the heading of live stock the total number of horses returned was 1,699,640, including 1,214,290 animals used for agricultural purposes. On the total there was a decrease of 142,920 in the number of horses. Cows and heifers in milk or in calf numbered 4,476,470, as compared with 4,576,850, a decrease of 100,380. Other cattle were accounted for as follows: Two years old and above, 2,217,760, a decrease of 108,820; one year old and under two, 2,655,570, an increase of 67,720; under one year, 2,781,570, an increase of 128,290. The gross total number of cattle is given at 12,131,370, compared with 12,144,560 in 1914, a decrease of 13,190. The total number of sheep was 28,181,540, an increase of 295,450 on the year, while pigs numbered 3,783,780, as compared with 3,939,890 in 1914.

Iron and Steel Institute. — The Autumn Meeting of the Institute will be held at the Institution of Civil Engineers, Great George Street, Westminster, on September 23rd and 24th. The following is the list of papers that are expected to be submitted for reading and discussion. (1) Wesley Austin, M.Sc., "Influence of oxygen on some properties of pure iron"; (2) T. H. Byrom, "Note on the carburisation of iron at low temperatures in blast furnace gases"; (3) Professor E. D. Campbell, "Influence of heat-treatment on the specific resistance and chemical constitution of carbon steels"; (4) Professor C. A. Edwards, D.Sc., and H. Kikkawa, "Effect of chromium and tungsten upon the hardening and tempering of high-speed tool-steel"; (5) W. H. Hatfield, D.Met., "Phosphorus in iron and steel"; (6) Professor K. Honda and H. Takagi, "The magnetic transformation of cementite"; (7) R. H. Smith, "Sulphur in malleable cast iron"; (8) Professor N. Tschischewski, "Iron and nitrogen."

Japanese Watch Crystal Industry.—A Japanese industry, concerning which little has hitherto been heard, is the manufacture of watch crystals. This is, perhaps, due to the fact that this class of goods has heretofore been purchased mainly from Germany and Switzerland There is, however, a firm in Osaka which is making these glasses in large quantities and exporting them to Manila, Shanghai, and Hong-Kong; the firm also supplies the watch dealers in Japan, Osaka being the distributing centre for the southern, and Tokio for the northern section of the Empire. The glasses are not made in one large factory, but at about fifteen places in Osaka the firm's workmen are manufacturing the glasses as a home industry. The wholesale prices per gross, delivered at Osaka ready packed for shipment, are: fine, 2*s.* 7*d.*; misconcoves, 3*s.* 8*d.*; roscop, 4*s.* 9*d*; round edge, 12*s.* 6*d.*; glass, 1*s.* 8*d.* The United States Consul at Kobe, in reporting the above particulars, remarks that he is unable to say how the quality of the glasses compares with those of European manufacture.

Chinese Wood-Oil in Florida.—The adaptability of the Chinese wood-oil tree for cultivation in Northern Florida seems to have been proved by recent experiments, says a United States Commerce Report. A tree at Tallahassee, Florida, bore two bushels of the fruit last season. In addition to being a tree of economic importance, it is a decidedly ornamental one, bearing clusters of white flowers with reddish-yellow centres, and in full bloom resembles a catalpa. The United States imports annually about 5,000,000 gallons of Chinese wood-oil, valued at $2,000,000 (about £400,000). As the demands of the American varnish trade are steadily increasing, this affords a very large domestic market for this prospective new Florida industry. The tree is *Aleurites cordata* (Chinese Tung yu), the seeds yielding the nut from which the oil is extracted.

Textile Production in Korea.—According to a statistical report of the production of textile fabrics in Korea in 1914, recently published by the Government-General, cotton cloth heads the list with 19,292,086 yards, valued at £806,000, and hemp cloth second with 13,441,087 yards, valued at £223,000. In addition to these, £562,000 worth of T-cloths, silk cloths, and other textiles were produced during the year. Practically all of these goods were produced by home industry, as there are no factories in Korea for the production of these articles.

Calais-Hankow Railway.—On June 16th work was commenced on the breaking through of the wall on either side of the Chien Men, for the purpose of making the two new gateways. The work is being undertaken with the object of making a central station for the Pekin-Mukden and Pekin-Hankow railways. It is interesting to note that when this work has been completed, and the two lines have been connected, it will be possible to go by rail direct from Hankow to Calais. This will form the longest railway connection in the world.

Journal of the Royal Society of Arts.

No. 3,279. VOL. LXIII.

FRIDAY, SEPTEMBER 24, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS.

The results of the 1915 Examinations have now been published in a pamphlet of 139 pages, folio, which can be obtained at the Society's offices, price 1s., or by post 1s. 3d.

They had previously been communicated to all the candidates.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

FOODSTUFFS.

By DAVID SOMMERVILLE, B.A., M.Sc., M.D.,
Assistant Professor of Hygiene and Public Health, King's College, London

Lecture III.—Delivered May 10th, 1915.

From the above brief outline of what is known of the few substances discussed, it will be seen that any true knowledge of metabolic processes can only be obtained by the tedious work of unravelling complex biochemical changes into individual chemical reactions. We will now glance at the more practical side of this subject.

Pettenkofer and Voit experimented on a fasting man, and from the amount of oxygen consumed concluded that the fasting organism supports itself by the combustion of its own protein and fat. They saw that the quantity of oxygen needed in metabolism depends on the kind of material burnt; that the "respiratory quotient" [ratio of CO_2 expired to O inspired as measured by volume, $\frac{\text{vol } CO_2}{\text{vol } O}$] when carbohydrates are oxidised is 1, when proteins burn 0·78, and when fats burn 0·71.

In writing of their work Voit says: "We found that in starvation protein and fat alone were burnt; that during work more fat was burnt; and that less fat was consumed during rest, especially during sleep; that the carnivorous dog could maintain itself on an exclusively protein diet, and if to such a protein diet fat were added the fat was almost entirely deposited in the body; that carbohydrates, on the contrary, were burnt no matter how much was given, and that they, like the fat of the food, protected the body from fat loss, although more carbohydrates than fat had to be given to effect this purpose; that the metabolism in the body was not proportional to the combustibility of the substances outside the body, but that protein which burns with difficulty outside metabolises with the greatest ease, then carbohydrates; while fat, which readily burns outside, is the most difficultly combustible in the organism."

Voit showed that muscular work did not increase metabolism, and that the metabolism was not proportional to the oxygen supply. His experiments showed that the absorption of oxygen does not cause metabolism, but rather that the amount of the metabolism determines the amount of oxygen to be absorbed.

Rubner, carrying on Voit's work in the Munich school by a series of most careful experiments in which all food and oxygen entering the body and all carbondioxide, water, urine and faecal matter leaving the body were controlled and accurately analysed, was led to formulate his famous isodynamic law, viz., that the foodstuffs replaced each other in accordance with their calorific value. That this law does not hold in all respects has been demonstrated by modern work.

Rubner drew another important conclusion, viz., that the heat value of the resting individual is proportional to the area of the surface of his body.

In connection with the analytical work Rubner found that the value of a gramme of dry faeces was 6·2 calories and was very constant, whether the subject was on a meat or a mixed diet.

The ordinary faeces indicate whether a given food is a small or a large faeces producer, but not how much or how little food has been used

by the organism. There is practically little or no difference between the digestibility and absorbability of animal and vegetable foods.

It has been stated that the cold-blooded ancestors of warm-blooded animals changed their habitat from the sea to the land in the tropics at a temperature which is now the inheritance of their descendants, and that in the course of development these animals acquired the power to maintain that ancestral temperature. The nervous mechanism by which this is effected is: (1) chemical regulation of temperature by which an increased production of heat appears in the presence of external cold; and (2) physical regulation of temperature by which variations in the quantity of blood supplied to the skin modify loss of heat through radiation and conduction, and variations in the amount of sweat modify the loss of heat by evaporation of water.

Heat is lost by conduction and radiation, by evaporation of water from lungs and skin, by warming food ingested and by warming inspired air. Roughly, heat elimination is proportional to surface exposed.

Cold baths increase metabolism. The respiratory quotient indicates that the increased metabolism is at the expense of glycogen. There is an after-effect which lasts about an hour and a half.

Experiment shows that if instead of natural foods purified materials such as egg albumin, casein, vitellin, starch and oleomargarine with the proper salts be mixed and given to animals the offspring are difficult to rear on the same food and no living young can be obtained from the second generation. Artificial foods cannot replace natural foods. The influences of protein food on nutrition are various: when protein alone is digested it is readily oxidised and only with the greatest difficulty deposited as new tissue.

If that quantity of meat be administered which is equal to what is oxidised in starvation nitrogen equilibrium will not be established, but some of the body tissue will also be metabolised. This last grows steadily if the amount of meat ingested be gradually increased till the point of nitrogen equilibrium is reached, at which the amount of meat ingested is equal to that destroyed in the body. Nitrogen equilibrium may be present whilst the body loses fat, *i.e.*, one may have nitrogen equilibrium without carbon equilibrium. A knowledge of this underlies systems of diet for the obese. In these cases loss of protein is undesirable, whilst loss of fat is the greatest relief. Gelatin contains almost as much nitrogen as protein; it yields the same amino-acids, with the exception o tryptophane, tyrosine, and cystine; in the diabetic it yields the same amount of sugar as protein; but no matter how much of it is ingested, it is all burnt and body protein in addition. Gelatin, therefore, never builds new tissue; it cannot be converted into protein nor act like protein in metabolism. Gelatin, however, like carbohydrates, spares protein. If the lacking tyrosine, tryptophane and cystine be added to gelatin in the proportions found in true protein the mixture maintains nitrogenous equilibrium in man and the dog.

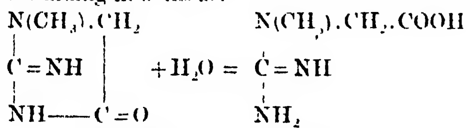
Abderhalden fed a dog with 25 grammes fat, 50 grammes starch, 10 grammes cane sugar and 5 grammes dextrose, and brought it into nitrogen equilibrium with meat containing 2 grammes nitrogen. He then substituted for the meat the amino-cleavage products of casein produced by pancreatic digestion, and also containing 2 grammes of nitrogen. For sixteen days there was an average daily gain of 0·12 gramme of nitrogen. He then hydrolysed casein by acid and administered the cleavage products as before containing 2 grammes of nitrogen. For ten days the dog lost 0·53 gramme of nitrogen daily. This is the experimental evidence of the statement above that acid hydrolysis cannot replace natural enzymic hydrolysis. Henriques hydrolysed protein with trypsin and erepsin, and then treated it with 20 per cent. H_2SO_4 on the water bath, obtaining amino-acids with no admixture of polypeptides. He found that as long as the mixture gave a pronounced tryptophane reaction it supported the organism in nitrogen equilibrium. In the absence of the single amino-acid tryptophane nitrogen equilibrium cannot be attained. In practical dietetics cleavage products of proteins have no value. Albumoses and peptones, when given in quantity, produce diarrhœa.

Serum albumin contains 7·7 per cent. glutamic acid; serum globulin 8·5 per cent. Abderhalden administered 1,500 grammes of gliadin containing 36·5 per cent. glutamic acid, but the percentage of glutamic acid in both constituents of the serum remained unchanged. A new construction of protein in the body from synthesis of amino-acids formed in digestion is characteristic of the organism and not of the proteins ingested. A copious drinking of water appears to remove accumulations of nitrogenous decomposition products and at the same time to cause a small but true increase in protein

metabolism. Abderhalden found that homogentisic acid is an exception to this rule in the case of the alcaptonuric.

Voit concluded that the cleavage of the protein molecule produced a nitrogenous and a non-nitrogenous portion, that the nitrogenous portion was rapidly burnt and that the non-nitrogenous part was temporarily stored for future combustion as needed. It has been shown that in diabetes the amino-acids are deaminised with formation of ammonia and organic oxyacids; these acids are directly available for oxidation or for conversion into dextrose. The heat and other energy values of protein lie in this denitrogenised remainder. Thiele has shown that in a cystinuric patient the same quantity of cystine is excreted in the urine, whether the patient be starving or fed with carbohydrates, with meat or with cystine which he has himself excreted. But the cystine of his own excreta and also that of meat were destroyed when ingested by the mouth. Thiele argues that this destruction occurred in the intestinal mucosa. The view most generally held by modern workers is that deaminisation occurs in the mucosa.

A diet containing a medium amount of protein produces no more creatinine and no more uric acid in the urine than a diet almost free from protein. This led Folin to distinguish an endogenous from an exogenous protein metabolism as represented by the urea eliminated which is in greater part derived from ingested protein. Creatinine is not influenced by muscular work nor by the increased protein metabolism following phosphorus poisoning. Creatinine ingested is largely eliminated in the urine. Mellanby finds that creatinine is not excreted in chickens until the muscles are saturated with creatine. Possibly the creatinine formed in metabolism is converted into creatine for building new tissue.



creatinine creatine

Normal urine does not contain creatine; creatine is not a product of endogenous metabolism. When ingested it may be destroyed or excreted in the urine, but not converted into creatinine. It frequently appears in the urine as an indication of destruction of muscle, *e.g.*, in involution of the uterus, carcinoma, fasting, phosphorus poisoning. We know nothing chemically of the origin of creatinine.

Creatine is the extractive found in largest quantity in muscle. In Liebig's extract it is largely converted into creatinine. It is ready for elimination in the urine, and is therefore of no value as a food.

The production of fat from protein was clearly demonstrated by Cremer, who starved a cat until its glycogen disappeared, and fed it on lean meat. The carbon of the meat ingested was calculated at the low ratio of 3·18 to 1 of nitrogen. There was a daily excretion of 13 grammes of nitrogen, corresponding to the liberation of 41·6 grammes of protein carbon. But only 34·3 grammes carbon were actually eliminated. The difference, 7·3 grammes, or 17·5 per cent. of protein carbon, was not eliminated. During eight days the whole carbon retention was 58 grammes, corresponding to 130 grammes of glycogen. The glycogen obtained when the cat was killed amounted to only 35 grammes. The difference must have been stored as fat. It is very possible that the origin of fat from protein is of the same nature biochemically as its origin from carbohydrates.

That animals can convert carbohydrate into fat has long been known. Weinland expressed ferments from living ascaris which convert glycogen into dextrose, and dextrose into valerianic and caproic acids. When carbohydrates are converted into fat in the animal the respiratory quotient may rise considerably above unity; an oxygen-rich substance is being converted into a substance poor in oxygen. The intramolecular oxygen of the carbohydrate becomes available for the formation of CO_2, and accordingly the requirement for inspired oxygen diminishes. Before the setting in of winter hibernating animals instinctively devour large quantities of carbohydrates.

Chittenden finds that nitrogen equilibrium can be maintained on a diet containing a very small amount of protein and two-thirds the body's requirement of energy. When Chittenden's practice is applied to obese patients, the other third of the necessary energy is furnished by the body's own fat.

Rubner showed that a man developing mechanical energy to the extent of 15,000 kilogramme-metres per hour, excretes the same quantity of CO_2, no matter what the temperature of the atmosphere may be. In other words, during mechanical work the influence of the "chemical regulation" of body temperature may be eliminated. The extra heat produced in performing mechanical work is utilised instead of the production of heat which is excited reflexly through cold.

It has been definitely settled by numberless experiments that muscular work does not increase protein metabolism, and that the character of the metabolism is not changed by muscular exertion. The total nitrogen and its individual constituents, the sulphur, etc., in the urine, remain unchanged despite the widest variations in degree of muscular activity. In this connection it may be mentioned that training has an influence on metabolism. A trained mountaineer performs his work at the expense of less metabolism than does the untrained. But training affects only the muscles involved in the particular movement and not those which remain inactive.

For a man doing average muscular work such as a soldier, Voit held that a normal diet should consist of protein 118 grammes, carbohydrates 500 grammes, fat 56 grammes. This diet produces 3,055 calories.

For men at hard labour this ration was considerably increased. Chittenden has disturbed the traditional view that for the maintenance of bodily vigour a liberal allowance of protein is necessary. He is of opinion that one-half the quantity of protein previously advocated is sufficient for the maintenance of excellent health. It is certain that large ingestion of protein in hot weather increases the heat production with increase in perspiration. In cold weather, however, an extra heat production may be of service. For man living in cold climates there appears to be no argument against the use of a medium amount of protein in accordance with the dictates of appetite. A dietary of 2,500 to 2,600 calories is not sufficient for a soldier at drill.

Milk, with its high protein content, is a food *par excellence* for the growing child, or the invalid convalescing from wasting disease. It contains too much protein for a normal adult. An exclusive milk diet is deficient in iron.

Milk alone has been recommended in the treatment of obesity in quantities varying between 1·5 and 2·5 litres a day. To meet a requirement of 2,400 calories daily, 3,400 grammes of milk would be required containing 140 grammes of protein.

A significant fact concerning the nutrition of the young is that the milk of a given race is *specifically adapted to the growth of the offspring* of that particular race. The milk of the bitch has an ash exactly the same in composition as that of the new-born puppy. The ash of this milk is therefore perfectly adapted for the building of puppy tissue. It differs, however, very considerably from human milk, or the milk of the cow or other animal. Again the caseins of different animals are different in their chemical behaviour. Also the rennin of the gastric mucosa is specially adapted for coagulation of the casein of the milk of the same race. The calcium content of cow's milk is in excess of the needs of the human infant. The differences in composition of human and cow's milk are so great that there is no escape from the conclusion that cow's milk is not to be substituted for human in rearing a child. Human milk, after the first month of lactation, contains a little more than 1 per cent. casein as against more than 3 per cent. in cow's milk. Cow's milk contains but little extractive nitrogen, whereas in human milk 18 to 20 per cent. of the total nitrogen may exist in that form. This is probably the reason for the $\frac{C}{N}$ ratio in the urine of breast fed infants reaching a figure greater than unity.

Fresh cow's milk and its serum are both acid to phenolphthalein, and alkaline to methyl orange. These reactions indicate that the acidity is due to acid phosphates. Phosphates cannot be titrated with any degree of accuracy in presence of calcium; some of the soluble dicalcium phosphate ($CaHPO_4$) formed during titration hydrolyses into calcium hydroxide and phosphoric acid –

$$CaHPO_4 + 2H_2O \rightleftharpoons Ca(OH)_2 + H_3PO_4.$$

The newly-formed calcium hydroxide reacts with more dicalcium phosphate to form tri-calcium phosphate

$$Ca(OH)_2 + 2CaHPO_4 \rightarrow Ca_3P_2O_8 + 2H_2O.$$

Dibasic phosphates are neutral to phenolphthalein. Monobasic phosphates are acid to phenolphthalein. Phosphoric acid acts, therefore, as a dibasic acid to phenolphthalein. The molecule of free phosphoric acid formed above increases the acidity of the milk containing dicalcium phosphate. If the fat and dicalcium phosphate be removed from the milk by a Pasteur-Chamberland filter the acidity of the serum is reduced to about one half. Mono-calcium phosphate may be correctly estimated by first removing calcium by neutral potassium oxalate. After treatment with potassium oxalate the acidity of the milk is the same as that of its serum. Thus two classes of compounds are met with, those in true solution and those in suspension or insoluble. The constituents wholly in solution are sugar, citric acid, K, Na, Cl. Those partly in solution and partly in suspension

are albumin, inorganic phosphates, Ca, Mg. Albumin seems to be adsorbed to a considerable degree by casein, so that only a part of it appears in the serum. Serum from sour milk, and milk to which formaldehyde has been added, contains nearly all the albumin. The insoluble filtered portion consists of Ca_3, casein, and $CaHPO_4$, not in combination. By treating milk with formalin, and whirling in a centrifugal machine, it is possible to effect a nearly complete separation between phosphates and casein (L. van Slyke and Bosworth).

Sikes finds that in human milk the average amount of P_2O_5 during the first fortnight of lactation is 0·0297 per cent., varying between 0·0140 and 0·0522 per cent.; that the percentage of the non-protein P_2O_5 averages 0·0169, and of the protein P_2O_5 0·0124; that the ratio of the protein P_2O_5 to the total P_2O_5 averages 42·3 per cent. He finds that the average amount of Ca in human milk in the first fortnight of lactation is 0·0301 per cent.; that the greater portion of the Ca is combined with the protein, as the ratio of the protein calcium to the total Ca is, on an average, 84 : 100. When both the Ca and the protein were estimated in the same samples, the Ca was found to average 1·06 per cent. of the total protein.

When it is considered that Ca, estimated as oxide, is found in cow's milk to five times the extent that it exists in human milk, it is easy to conceive that the assimilation of cow's milk by the infant is a very different proposition from assimilation of that of the breast. The large quantity of calcium alters the characters of the casein in relation to rennin and the proteoclastic ferments.

Osborne and Mendel have pointed out the dominant importance of certain amino-acids in the problems relating to the function of the nitrogenous intake in both maintenance and growth. When the content of any essential amino-acid group in a given protein is small, this poverty will not be manifest so long as the diet contains a surplus of this amino-acid above the figure required for maintenance or growth. But on lowering the plane of protein intake a level will be reached where the quantity of the essential amino-acid becomes so small that it cannot satisfy at first the requirements of growth, and later the maintenance need. In other words, the amount of protein available at any time for functions of growth will be limited by the "law of minimum."

It is known that casein yields little cystine. When the diet contains 18 per cent. of casein, together with the essential non-protein components, young rats can complete their growth satisfactorily. With 15 per cent. casein growth is maintained normally. Below 12 per cent. growth falls off slightly. When casein falls to 9 per cent. growth promptly goes down. When cystine to the amount of 3 per cent. of the casein is added to the ration growth progresses favourably.

On 4·5 per cent. casein growth is maintained for a little and then goes down. On 2 per cent. casein growth sharply declines from the first. But cystine is unable to retrieve the failure in growth when casein reaches a level somewhat below 9 per cent.

In the same way it has been shown that edestin which is poor in lysine, can secure normal growth when administered in quantities constituting 15 per cent. of the ration. With 12 per cent. growth is diminished. The addition of lysine, equal to 2 per cent. of the edestin, makes good a normal growth.

No amount of zein food, however large, will retain rats in nutritive equilibrium. A small amount of tryptophane will convert the inefficient ration into an efficient one.

A content of protein utterly inadequate in the case of casein allows good growth when lactalbumin is added.

Young rats fed on purified protein, carbohydrate in the form of starch, and inorganic salts in the form of protein-free and fat-free milk, together with lard, grow normally for about three months, but never attain full size. Sooner or later decline in body weight occurs, with symptoms of malnutrition (eye infections and impaired resistance to bacterial invasion). If instead of lard, butter fat, egg yolk fat, cod-liver oil, or beef fat be used recovery promptly follows. Almond oil and olive oil give negative results. Attempts have been made to separate the "active" substance at work in promoting growth in these fats. Osborne and Mendel have concentrated it by dissolving the fat in alcohol and cooling it to -15°, at which low temperature the higher melting fats crystallise out. The clear alcoholic solution is concentrated at 40° *in vacuo* until the alcohol is completely removed. The growth-promoting properties appear to reside in the clear yellow oil which is left, and not in the white crystalline solid obtained as above.

Failure of nutrition on diets containing lard has been completely restored by the substitution for lard of butter fat, butter oil as above prepared, or commercial oleomargarine.

Osborne and Mendel have published charts

showing the extent to which small proportions – 1 per cent., 3 per cent., 6 per cent.—of butter fat are efficient in promoting growth and to which larger proportions restore growth after decline.

McCollum and Davis publish curves to show that the lowest plane of protein intake derived from milk which can maintain young rats without loss of body weight is 3 per cent. of the ration.

As the plane of protein intake is raised between 3 per cent. and 8 per cent., there is a progressive increase in the rate of growth.

If protein derived from wheat kernel be supplied to the extent of 6 per cent. of the ration, growth takes place at about half the normal rate. A ration containing 4 per cent. of protein from wheat embryo is somewhat better than a similar ration containing 6 per cent. protein from the entire kernel.

Casein and ovalbumin are rich in lysine and promote maximal growth; while zein fails to do so because of its lack of lysine and tryptophane.

These two substances have been shown to spare body protein more than others.

Fully 80 per cent. of ingested proteins and nearly 60 per cent. of body proteins are converted into glucose in the phlorizinised animal. This transformation may be considered as a normal process. The protein-sparing function of carbohydrate has long been known; and it is now clear that utilisation of protein depends on the presence of carbohydrate. Dakin regards oxyaldehydes as metabolites closely related both to amino-acids and glucose. It may well be, as Janney suggests, that glucose and amino-acids break down into oxyaldehydes and ammonia, from which new proteins are synthesised; and that the demand of the starving body for glucose may be but an expression of its need for protein repair. In the later stages of starvation it is probable that the organism uses the degradation of the protein of lower organs for the synthesis of that of higher.

The fact that various proteins yield large amounts of sugar in the diabetic phlorizinised dog has been fully established; and that individual amino-acids yield sugar has also been established. The following amino-acids yield sugar: Glycine, alanine, serine, cystine, aspartic acid, glutamic acid, ornithine, proline. The following are non-glucogenetic: Valine, leucine, isoleucine, lysine, phenylalanine, tyrosine, tryptophane. Whilst unable to produce sugar leucine, tyrosine, and phenylalanine yield an increase of aceto-acetic acid. Janney, in a recent paper, has shown (1) that vegetable and animal proteins under optimal conditions are metabolised at the same rate in the animal organism; and that all the extra glucose and nitrogen are eliminated by the ninth hour after ingestion. (2) Each protein produces a definite amount of glucose in the phlorizinised organism. The various yields represent 50 to 80 per cent. by weight of the protein administered. These yields approximate the ratios which the glycogenetic amino-acids of the proteins in each case bear to the total amino-acids as actually determined by hydrolysis.

Moorhouse, Patterson, and Stevenson find that in experimental diabetes produced by removal of the pancreas, the total metabolism is increased, and the increase corresponds in quantity with the intensity of the characteristic symptoms. This increase ranged from 9 to 38 per cent. The rise of the respiratory quotient which normally occurs after ingestion of glucose or fructose is greatly diminished, or is absent after total removal of the pancreas, indicating that complete oxidation of sugar does not occur. The increase in the excretion of acetone bodies is parallel with the increase in the Dextrose : Nitrogen ratio and with the total metabolism suggesting that the phenomena are expressions of a similar disturbance of protein metabolism, which is secondary to the impairment of sugar utilisation.

Rubner and Richet, adopting the view that heat is produced in the body in order to maintain its temperature at the necessary level of 37° rather than as an incidental occurrence consequent on the degradation of energy, taught that the heat production of animals is directly proportional to the body surface, and that in several groups of animals approximately 1,000 calories per square metre are liberated daily; moreover, that each kilogramme of body substance has the same heat-producing power as every other kilogramme throughout the body. It is known that the surface of irregular but similarly shaped bodies varies as $\sqrt[3]{\text{volume}^{(2)}}$. Benedict, using this formula, collected evidence in his nutrition laboratory to show that the law of heat production per square metre of body surface does not obtain. On the contrary, from data obtained through observations on eighty-nine men and sixty-eight women, all in apparently good health, he found the variations in heat output so large as to exclude all possibility of the existence of any such law. By plotting the total metabolism as measured by the total twenty-four hour heat production against the

body weight, and in like manner heat production per kilogramme of body weight against body weight, nothing in any manner approaching constancy in relationship was found. In man, *e.g.*, heat production per kilogramme of body weight varied over a range of 60 per cent. or more, and in women over a range of 80 per cent.; whilst heat production per square metre of surface varied in men over a range of 40 per cent. and in women over that of 43 per cent. The simple relationships assumed to exist between the size of the body and its heat-producing mechanism, and between the area of the body and its heat requirement are thus shown to be non-existent.

Metabolism is affected in a variety of ways: (1) By variations in the mass of active protoplasmic tissue. Benedict and Smith quote figures to show that in trained athletes basal metabolism according to the three standards of comparison, viz., total metabolism, heat production per kilo of body weight, and heat production per square metre of body surface—is measurably greater than in non-athletic individuals of the same weight and height. (2) By variations in cellular stimulation. Men weighing 50 kilos have been found to produce more heat per square metre of body surface than others weighing 80 kilos. (3) Youths have a very much higher metabolism than adults. (4) Sleep in one case studied showed a lowering of 13 per cent. in the metabolism on the waking hours. (5) Diurnal variations. If the metabolism during the night be taken as a basis, an increase is found in the morning of 13 to 14 per cent. and the late afternoon of 22 per cent. (6) Fasting. After the twenty-third day of a fast the metabolism rose. The tendency to depress metabolism due to previous continued loss of protoplasm by fasting was actually at this date overcome by the unknown stimulus increasing the cellular activity of the remaining body substance. (7) Character of diet. With the acidosis which results from ingestion of a carbohydrate free diet there is a distinct increase in basal metabolism; acids stimulate the cellular activities. (8) Severe muscular work. As a result of excessive muscular activity cellular activity may be increased enormously and maintained at a high level for a considerable period after cessation of work, with a corresponding high though continually decreasing plane of metabolism. It appears then, from accurate measurements made on athletes and on normal men and women, that the metabolism, or heat output of the body, even at rest, does not depend on Newton's law of cooling, and is not proportional to body surface; but that the proportion of active protoplasmic tissue to inert body fat is important (the greater the proportion of active protoplasmic tissue the greater the metabolism). With this must be considered the stimulus to cellular activity as modified by sleep, age, period of the day, fasting, character of preceding diet, and muscular work. No law, however, can be at present stated to cover these two important variables in the basal metabolism of the individual.

Benedict has still more recently studied the metabolism of athletes as compared with normal individuals, when he made observations on the basal metabolism in a post-absorptive state with the patient at complete muscular rest. Each experiment was commenced twelve hours after the last meal. He continued this research to men as compared with women. He found that athletes have a somewhat higher metabolism than non-athletes; and he concludes that the increased proportion of active protoplasmic tissue present in the trained athlete is alone sufficient to account for this increase; and that the catabolism of the body is proportional not to the surface of the body, but to the active mass of protoplasmic tissue. The metabolism of women in middle life is the same as that of men of the same age and body weight. With children and old men and women females have a slightly less metabolism than males. But he finds no law governing the relationship between the total body weight and the total heat production.

Little is known of the chemical changes which take place in foodstuffs that are kept, even under the best conditions for considerable periods of time. Some time ago I investigated the nitrogenous metabolism of growing white rats fed on a diet of crushed wheat three years old. The same number of controls (three) from the same litter were fed in the same manner, on grain three months old. The urinary analyses made were: Total N by Kjeldahl's method, ammonia by Folin's method, urea by the method of Ronchese, creatinine and uric acid by Folin's methods, and P_2O_5 by Neumann's method.

During the six weeks of the experiment the metabolism of the animals fed on the old grain failed in all cases to reach that of the controls fed on new grain, and growth failed to the extent of from 20 to 30 per cent. Urea nitrogen was in all cases lower. In two of the three animals fed on old grain ammonia was in the

average 15 per cent. higher than in the controls. Total nitrogen fell below that of the controls 22 per cent. (mean of 18, 23 and 25 per cent.). P_2O_5 failed to reach the level of that in the controls by 5 per cent. The amounts of creatinine and uric acid were exceedingly small, the latter so small in two of the cases as to be scarcely possible of estimation: in the case of these items also the figures were larger in the controls. I hope to be able to show that one factor in this problem, which may to some extent account for the lowered metabolism, is the increased resistance to proteolytic hydrolysis found in the old grain.

One other remark before leaving the subject of metabolism: whilst it is quite true that a large protein dietary raises the plane of metabolism generally, and protein metabolism in particular, it is reasonable to assume that the increased wear and tear thrown thereby on the body mechanism may, in many cases, make for a premature disorganisation of tissue in important vital organs, thereby shortening the tenure of life. This matter will be referred to later in connection with the putrefactive fermentation of proteins in the intestinal tract.

INDIAN FORESTS.

The quinquennial review of the Forest Administration in India contains a useful summary of the progress that is being made in the development of the forests, which cover no less than a quarter of a million square miles. As regards paper manufacture, the report shows that an encouraging advance has been made. It says that with the assistance of the Titaghur Paper Mills Company, trials in the manufacture of bamboo pulp have been carried out successfully on a commercial scale, and concessions for the extraction of bamboos have been granted to two firms in Burma and Bengal. The outbreak of war has delayed the commencement of manufacture, but as large supplies of the raw material are available the outlook is promising. In the Punjab a concession for the extraction of spruce and silver fir from the Kulu forests for the manufacture of wood pulp has been granted. Matters are less advanced as regards the grass-pulp industry, but this is being seriously considered. In the United Provinces and Assam enormous quantities of suitable grasses are available, and if trials on a commercial scale be successful an important industry may be established.

The extraction of tanning materials has received attention for some time past, particularly in the matter of obtaining a satisfactory extract from the bark of mangroves. For this purpose a factory was established several years ago at Rangoon, but owing to the want of expert supervision was not very successful. In order to test the possibility of producing extracts of good quality on a commercial scale the services of a tanning expert have been obtained and he will probably reach India shortly, bringing with him a small portable plant. The forests of India contain many valuable tanning materials other than mangrove bark. The possibility of utilising these will be examined by the expert, and his appointment may result in the establishment of a new and important industry.

Another important forest industry in which the report shows that marked progress is being made is that of rosin and turpentine production from pine trees. In the Himalayas, in the Punjab and the United Provinces, distilleries have been established, and are now turning out considerable quantities of both rosin and turpentine. The Indian demand for these products, which are largely used in the manufacture of paper, paints and varnishes, is considerable, and the local outturn has already affected imports from other countries. In the Punjab a modern plant has been erected near Lahore and a large increase in the outturn is also expected in the United Provinces.

As regards finance the surplus average revenue per annum in the past five years has been 132 lakhs, as compared with 116 lakhs in the preceding quinquennium, and the report shows that during the past fifty years the surplus has increased nearly ten-fold. These remarkable results are in spite of the fact not only that a substantial portion of the annual expenditure is absorbed by the cost of research and of sylvicultural work, for which no immediate return can be expected, but also that all capital expenditure is met from revenue. There is, too, the fact that each year large quantities of forest produce are given away free or removed by right-holders. The average annual value of the produce so removed is over 62 lakhs of rupees, but this is a rough estimate only and does not represent the amount which would have been realised had the produce been sold. Both in 1912-13 and 1913-14 the surplus was over a million pounds sterling, and the report anticipates that in the near future this figure will be exceeded.—*Times of India.*

CANADIAN MOLYBDENUM.

In view of the great demand for molybdenum, which is indispensable in the production of certain grades of steel, attention is being drawn to Canada as a source of supply. Although it is found in numerous localities throughout the country, there has as yet (according to the Report of the Canada Department of Mines on the Economic Minerals and Mining Industries of Canada) been practically no recovery of the metal in Canada, with the exception of small amounts obtained while developing or exploring properties. Molybdenite deposits in Canada are usually found in the Archaean regions, and are probably due to the influence of masses of granite. Molybdenite occurs in quartz veins, pegmatite dikes (probably connected with the granite masses), and along

contact borders of granite or pegmatite with crystalline limestone.

The most promising deposits, as they were to be seen in 1909 and 1910, were situated in the following places: an island opposite Romaine, Lower St. Lawrence; Aldfield and Egan townships, north of the Ottawa River; the vicinity of Kewagama Lake in the northern part of Pontiac county, Quebec, near the Grand Trunk Pacific Railway; Brougham, Lyndoch, and Ross townships in Renfrew county, Sheffield township, Addington county, and Cardiff township, Haliburton county, in Eastern Ontario; and the Giant Mine, Rossland, British Columbia.

A note about the occurrence of molybdenum in Australia appeared in the *Journal* of May 7th, 1915. It is important that any deposits of the metal within the British Empire should be located, as hitherto we have been almost entirely dependent on Germany for our supplies.

OIL IN CHINA.

In the course of a brief survey of the world's supplies of petroleum, some account is given in the volume on "Petroleum and Natural Gas Resources of Canada," published by the Canadian Department of Mines, of the oil industry in China. Oil occurs chiefly in the Shensi Province, where it has been obtained in small quantities for centuries. At present trifling amounts are obtained by antiquated methods and used locally. In the eastern side of the province there are oil-mills worked with rudimentary machinery under Japanese supervision, but the yield of the wells is small owing to the methods in use. Petroleum, natural gas, and salt-brine deposits are reported by travellers in the interior of the country, but it seems certain that for many years to come China will depend for its supplies of oil upon other countries.

For many centuries in the province of Szechuen, wells from 2,500 to 3,000 ft. in depth have been drilled by a most primitive and laborious method. These have yielded large quantities of salt brine, and natural gas and petroleum in limited quantities, the natural gas being used extensively as fuel to evaporate the brine. The petroleum is of four different qualities. The first is of a very light colour, and is used in its natural state for burning with refined petroleum in special lamps, the second is of a very greenish colour, and is less valuable than the first, the third is yellow; and the last is black, very thick and viscous. The first is also employed by the Chinese for medical purposes, especially for skin diseases and rheumatism. The temperature of the petroleum and brine as they come from the wells is about 250 C., while the temperature of the atmosphere is only about 40 C.

In general the petroleum occupies second place. The salt industry is ancient and is developed. Petroleum production is only of recent date and a side-issue of the salt industry. The refining processes are rudimentary, where they exist at all, and the oil is not sold commercially for illuminating purposes.

Many of the wells are on the side of a hill, which permits of the utilising of the natural fall, whether for running off the salt water into the reservoir and evaporation pans, or for conducting the gas given off from the salt wells, which serves like petroleum for fuel. All the conduits for water, gas, and oil are of bamboo. The work of drilling the well is conducted thus. An ordinary pit is dug until it reaches hard clay, which is usually found at a depth of 200 to 300 ft. In this a wall is built, cone-shaped at the top and with an opening large enough to admit the passage of the cable of a drill. Starting with the first hard layer, the drilling is carried on with a drill, the width of a section being 5 in. × $2\frac{1}{2}$ in. and 20 ft. long, and weighing a little over 130 lb. The strokes are thirty blows to a minute, falling each time 16 in. The last layer before reaching the salt-water stratum is granite and very hard. In some mines the brine is thrown very high into the air when the last layer is pierced, but only for a short time. Any natural gas found with the water is separated and sent by a main pipe to be divided to various salt pans for heating. Certain wells strike rock-salt, in which case a second well is drilled alongside the first, and sweet water is sent down to dissolve the salt.

The largest and one of the oldest springs of natural gas is at Tse-liu-tsin, while that at Chu-pai ching has been in operation day and night for forty years. As much as 400 or 500 lb. of fetid oil, which burns on water, may be obtained from a well in a single day. When a well produces petroleum alone the oil is conveyed to special reservoirs, but where it is found mingled with the brine it floats on the top of the liquid and is skimmed off. Where gas is the chief product of a mine well all the others are neglected. The gas appears to come from two separate horizons—one comparatively near the surface, and the other at a depth of about 720 yards.

ARTS AND CRAFTS.

The Schools. Most of the London schools of art are beginning work this week. Some, more especially the trade and technical schools, both in London and elsewhere, have already settled down to their autumn's work. In most cases the prospectuses are much the same as usual, with here and there a notice that such and such classes are "temporarily suspended." On the other hand, most people are wondering how far the proposed syllabuses will be carried out, and some teachers have been given to understand that there is at least a possibility, not to say a probability, of their classes not being held. If sufficient students present themselves, well and good, but at a moment when the cry is economy it is hardly likely that there will be any bolstering up of doubtful classes. This all seems reasonable enough, if a little hard

upon the teachers involved. We are at war, and we cannot blink the fact. However desirable it may be in normal times to encourage people of leisure to turn their attention to art and the artistic crafts, or to urge young people to take up some more or less artistic hobby as an occupation for fingers which might in their spare time find plenty of mischief to do, there is no need for that kind of thing at present. Older people's spare time can for the moment more profitably be given to war work, whilst the superfluous energy of the average small boy is finding plenty of outlet in scouting, drilling, and the like. In face of all this, some people are inclined to question rather wearily the advisability of continuing art and craft classes on a large scale, and to look upon energy devoted to art as rather misplaced. The idea is easy to understand. Art certainly appears more remote from any practical connection with the war than almost any other subject, and now that we have come to the point when the cry of "Business as usual" is out of favour, there seems little place for art and artistic craftsmanship. However that may be, this much is certain: we cannot expect or desire the schools to be as full as usual, or to be attended by quite the same type of students. But for all that, we can look upon them as doing good service, and that in at least three ways. They are, it is to be hoped, training serious students who will be ready when the stress is over to help, by doing their share, towards seeing that the design of our manufactured goods is better than it has ever been before, and is in fact of such a quality that it will enable us to take all those opportunities which we trust will be ours at the end of the war, and turn them to good account. Further, they are training in ways of craftsmanship boys (such as trade scholars and the like) who are too young for the fighting line, and girls of about the same age who will be infinitely more useful later on, whatever may be the fate of their own particular craft, for having learnt to handle tools with the precision and dexterity which an artistic craft demands, and will be able to uphold the traditions of British craftsmanship. Again, we can look to them for help with the difficult problem of the men who have been discharged from the army, wounded. That statement requires some qualification, of course. The artistic crafts have suffered in the past from the well-meant efforts of philanthropists obsessed with the idea that they offered suitable occupation for the halt, the maimed and the blind, as well as for weaklings of all kinds; and competent authorities in the various industries concerned have reiterated with persistence and reason that this idea is a mistake. On the other hand there are now men—there will probably be more of them later on—who, though incapacitated for military service, are neither weaklings nor cripples, and many of them are young enough to learn a craft successfully. It would, of course, be a mistake to flood the market with craftsmen at a time like this; but there ought to be room for some of these men in the ranks of hand-workers following a more or less artistic calling. Further, from a broader point of view of the situation, though art may seem for the time being almost out of place, it is in reality sorely needed. There is much ugliness around us on every side, and we can do with all the beauty that we can secure.

Woodcarving.—The School of Art Woodcarving, 39, Thurloe Place, South Kensington, S.W., always opens early in September, and is by now hard at work. Though it is one of those institutions which might have been expected to suffer very severely from the war, it did remarkably well this year at the National Competition, gaining thirteen awards in all, including a Princess of Wales's Scholarship and one gold and one silver medal an extraordinarily high number for a school of its size and it has begun work with a good number of students. These include the boy trade scholars, who are learning to be professional carvers, and women fee-paying students, some taking the full course, and others devoting only part of their time to carving The older art scholars of military age have naturally not had their scholarships renewed, and rather fewer evening classes are being held this session than usual. Of the boys who have recently completed their time in the school, several are in the army, and others are doing work for which their training has helped to fit them. One hardly expects woodcarving to be in demand at present, and a good many carvers have turned their attention to army work more or less connected with their craft, such as pontoon-making and covering cases to hold shells. On the other hand, some shops have work to do, and orders are still being executed for America. Woodcarving is not usually looked upon as an export, but of recent years some of the best English work has been commissioned for the States, and it is satisfactory to note that the war has not put an end to the trade, more especially as in days to come the United States will, presumably, have more money to spend than we shall. It will, of course, be found when things return more or less to their normal course that the war has dislocated the trade, but, as far as it is possible to judge at present, the condition of affairs will be more satisfactory than might have been expected, and, while it cannot be anticipated that during the continuance of the European struggle there will be any large demand for woodcarvers, the trade gives promise of being able to hold its own.

Lace.—There are, perhaps, few industries that have been more affected by the war than lace-making. After years of steady work, the craft, which had for some time been in a languishing condition, had been revived in different parts of England and Ireland and was beginning to find itself established on a satisfactory basis. Honiton, Buckingham, and Limerick lace were being made in fairly large quantities, and various Italian and

Belgian laces were being copied to good purpose; in short the English handmade lace industry had made a place for itself. It is still keeping that place, but recent events have not tended to make its task easier. Handmade lace is a luxury, the best of it a very expensive luxury, and the demand for luxuries does not expand in war time. Further, the devastation of Belgium, a country in parts of which nearly every woman was more or less of a lace-maker, thoroughly upset the normal conditions of the market. At a moment when common humanity demanded that many Belgian lace-makers, both over here and in their own country, should be provided with work, London at any rate was flooded with Belgian lace hastily brought to this country out of reach of the invader—much of which was sold at a price ridiculously below its ordinary value to folks who had some sort of hazy notion that they were doing an act of charity in buying it. Now that the first rush is over, it seems time to consider the question of co-ordinating in some way the English and Belgian industries and making some effort to see that prices are maintained at such a level that lace-making will not become a sweated industry. The Anglo-Belgian Lace Hostel at 47, Upper Brook Street, founded by Mrs Inglefield under distinguished patronage, tries in some measure to do this. A number of Belgian lace-makers are housed on the spot, where they may be seen at work under thoroughly good conditions any afternoon between three and five o'clock, and their work, together with that of Belgian outworkers, married women and others with home ties, is on sale on the premises. There is a competent teacher at the hostel who has already been down to Buckinghamshire to teach the making of *valenciennes*. The stock at the depot includes also excellent cut work, the output of Miss Hill's industry at Taormina, and some Italian filet as well as a good collection of Buckingham lace, examples from the Folkestone industry, and some Essex needle-run. Apparently the English work is selling quite well and holding its own, but it is rather a pity that while the Belgian exhibits include not only the cheaper kinds of bobbin lace but also *point de gaze duchesse*, rose point and other sumptuous needle point, the finer kinds of English lace are not represented.

NOTES ON BOOKS.

RIVINGTON'S NOTES ON BUILDING CONSTRUCTION. Edited by W. Noble Twelvetrees. London: Longmans, Green & Co. In two parts. 7s. 6d. net each part.

"Rivington's Notes on Building Construction" were published originally in 1875, and since that time they have been a boon and a blessing to architects. Part I. has been revised on six occasions, but during the lapse of the last ten years or so building construction has developed in many directions. Reinforced concrete and steel-framed buildings, for instance, have come into great prominence, and new materials of many kinds have been introduced, so that, in order to bring the book up to date, it has been necessary entirely to rewrite it. The general editing has been entrusted to Mr. W. Noble Twelvetrees, who contributes a number of chapters, while the rest of the book is the work of well-known architects and others, with special knowledge of the subjects which they deal with.

The work is divided in two parts: The first is concerned with matters requiring attention before the commencement of building operations, and then with forms of construction by the aid of which buildings of different types can be carried up from foundation to roof level. Part II deals with roofs and classes of work which pertain to the finishing of buildings for occupation and subsequently with various branches of engineering. It will thus be seen that the book is a complete *vade mecum* for the architect, and the names of the contributors, which include some of the most distinguished members of the architectural profession, are a guarantee of the excellence of the various sections.

SALT IN CHESHIRE. By Albert F. Calvert, F.C.S. London: E. & F. N. Spon, Ltd. 21s. net.

Cheshire has been known as a salt-producing country for two thousand years, the first open pan having been erected there by the Romans, but in spite of this remarkably long and continuous history, no attempt has hitherto been made to present a consecutive and logical account of it. Salt-makers, according to the author, have always shown a strong aversion from publicity, and persons exhibiting a desire for information on such subjects as depth of shafts, results of borings, levels of brine, quantities of rock-salt won and brine pumped, have been regarded with suspicion and disfavour. No little credit, then, must be accorded to Mr. Calvert, who, in spite of these difficulties, has succeeded in collecting from all manner of sources an extraordinary amount of information dealing with the many aspects of the subject. His book runs to between 1,100 and 1,200 pages. After a preliminary chapter on the chemistry of salt, he gives in great detail the early history of the Cheshire salt industry, illustrated by a number of quotations from contemporary documents. Special chapters are devoted to theories of the formation of the Cheshire salt deposits, the area of the beds, the top rock mines, and the growth of the industry, while a very full account is given of its later development.

Not the least interesting section of the book is that devoted to the Cheshire subsidences. Mr. Calvert's first reference to this alarming phenomenon is dated 1533, when "a pease of a hill having trees on hit" sank, and a pit containing salt water was formed. From that date the subsidences have become more and more frequent, and a large

number of photographs illustrate very vividly their extensive and dangerous nature. In some cases houses are seen sinking below the level of the street, or inclining at all sorts of extraordinary angles; in other cases large tracts of agricultural land are shown converted into briny marshes; while in others, again, whole streets are being raised to keep them above the water level. The damage done by these subsidences has been enormous, and the legal questions arising therefrom have been numerous and keenly contested. Bills dealing with the right of land owners to pump, and of house owners to compensation, have been many, and into all these the author goes very thoroughly.

If the Cheshire salt industry has had to wait many years for its historian, it has not waited in vain; for Mr. Calvert has been daunted by no difficulties in securing and presenting the fullest information, and his work may fairly be described as monumental.

WIRELESS TIME SIGNALS. London: E. & F. N. Spon, Ltd. 3s. 6d. net.

This is a translation of the French official handbook, "Réception des Signaux Radiotélégraphiques par la Tour Eiffel," which has proved of great value to navigators, geodesians, explorers, and horologists. A very clear account is given of the wireless apparatus, ordinary and scientific time signals, and the methods of calculating comparisons by means of the scientific time signals. The original French version is so well known and appreciated that the English translation may be sure of a welcome. The translators add some useful appendices on weather reports and international signals

GENERAL NOTES.

SCHOOL OF ART WOODCARVING.—At the School of Art Woodcarving, 39, Thurloe Place, South Kensington, some of the free studentships in the evening classes, maintained by means of funds granted to the school by the London County Council, are vacant. The day classes of the school are held from 9 to 1 and 2 to 5 on five days of the week, and from 9 to 1 on Saturdays. The evening class meets on two evenings a week. Forms of application for the free studentships and any further particulars relating to the school may be obtained from the Secretary.

NATIONAL COMPETITION, EXAMINATIONS IN ART, AND AWARDS IN ART, 1916.—In view of the urgent need for national economy and other circumstances arising out of the war, the Board of Education will not hold a National Competition in 1916. They hope to hold the examinations in art as usual, and have issued regulations for 1916 accordingly. They desire, however, to give notice that it may prove necessary at a later date to suspend the examinations. The interim regulations for scholarships, exhibitions, free studentships, and other awards in art applicable to the year 1914 are provisionally continued in force subject to certain modifications. Notice is also given that at some future date after the conclusion of the war one further special examination will be held for the benefit of candidates who had almost completed the requirements for the Art Class Teacher's Certificate and the Art Master's Certificate when the old regulations expired. The detailed arrangements will be announced in due course, and at least three months' notice will be given of the special examination.

NEW ZINC FACTORY FOR JAPAN.—The zinc industry of Japan is still in its infancy, there being only two factories—the Amagasaki Zinc Factory and the Mitsui Bussan Kaisha Zinc Refinery. Since the outbreak of war the imports of zinc into Japan from Germany and Belgium have been totally suspended. Naturally, the price of the metal, which ruled at £24 per ton before the war, has risen steadily, and now rules at over £40 per ton. In Siberia there are large zinc mines, the output of which has hitherto been forwarded to Germany and Belgium. With the opening of hostilities the supply of zinc ore to Europe became impossible, and prices fell considerably. Taking advantage of this, says the *Japan Gazette*, the Mitsui Bussan Kaisha recently entered into an arrangement with owners of zinc mines for supplies. It is stated that a big zinc factory will be established in Japan in the near future, under the auspices of merchants interested, with a view to meeting the demands on the domestic market.

MEMORIAL TABLETS. THE FIRST ENGLISH THEATRE.—The first building erected in London specially for the performance of plays was known as "The Theatre." Its site had not hitherto been determined with precision upon satisfactory evidence, but a detailed investigation was undertaken under the auspices of the London County Council, and a booklet containing an account of the inquiry has just been published. The building was erected by James Burbage, a leading member of the Earl of Leicester's players, in 1576. The most meticulous care has been taken to verify the site, which was on a plot of ground bounded on the west by Curtain Road, on the south by New Inn Yard, and the east by New Inn Broadway, Shoreditch. The Theatre existed for twenty-two years. Among the pieces acted there was Marlowe's "Faustus." It is not clear that any of Shakespeare's plays were ever performed in the Theatre, though there seems reason to believe that Shakespeare himself, as a member of the Lord Chamberlain's company, often acted there. The Theatre fell into disrepute, and after a series of quarrels it was pulled down in 1598, when the materials were carried away to the south side of the Thames and used in the construction of the Globe. It is probable that after the war a memorial tablet will be affixed to the wall of the Curtain Road School, Shoreditch, commemorating the fact that the Theatre once stood within a few yards of the spot.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

FOODSTUFFS.

By David Sommerville, B.A., M.Sc., M.D.,
Assistant Professor of Hygiene and Public Health, King's College, London

Lecture IV.—Delivered May 17th, 1915.

With some of the above considerations in mind we may retrace our steps and look again at the structure, the molecular structure of the cell, the unit of bioplasm. This complex may be regarded as a machine in which there is a constant flux of energy. In it absorption, transformations and redistribution of energy proceed unceasingly, whilst structural changes in its life history march but slowly.

In order that oxidation of the various food-stuffs contributed by the environment may proceed freely, it is essential that the integrity of the cell be preserved by the proper adjustment of all the necessary organic and inorganic constituents. The inorganic constituents are as important as the organic. When inorganic ions are altered so that the running equilibrium between protoplasm and ion is destroyed cell activities cease. Ringer demonstrated, in the case of the muscle of the frog's heart, the indispensability of the inorganic ions. Function can only continue in the presence of the proper osmotic concentration of the saline solution perfused; but the osmotic concentration is not the only condition; there are definite limits to the amounts of the individual ions essential to the continued existence of the cell. An isotonic solution of NaCl may wash out of the cardiac muscle potassium and calcium ions to such a degree that, although sufficient oxidisable organic material be present for the liberation of the necessary energy, the whole architectural fabric of the cell falls to pieces. It has been shown that the quantities of potassium and calcium required are exceedingly small (KCl 1 in 10,000), and that the working range of concentration in either direction is exceedingly small, otherwise the heart ceases to beat.

In the cold-blooded animal the oxygen tension of the atmosphere is sufficient to maintain for a lengthy period cardiac activity if adjustment of the inorganic ions be correct. In the case of the mammal the oxygen tension must be raised to nearly that of an atmosphere of pure O by passing O through the warmed saline solution used. This increased O pressure supplies the place of the red blood corpuscles.

What we have learnt from the reactions of cells leads to the conception that the intermixture of proteins, carbohydrates, fats, and inorganic ions forms a system but lightly held together, each component kept in position by the pressure of a free part in the fluid which bathes the cell, an inexorable condition being that the osmotic pressure of each constituent lies within the narrow range proper to it. It would appear that in this labile equilibrium of varying intensities of attachment amongst the constituents, proteins, fats and carbohydrates undergo molecular disruption, that oxygen unites with them, and when the pressure of the oxidised products reaches a certain height these bodies pass away from the cell. The perpetuation of such labile equilibrium appears to be a necessity to life. In the protein molecule, largely constructed of amino-acids, we have an ideal combination for the attainment of this end. The amino-acid contains both a basic and an acidic radical "two opposite poles, as Moore puts it"—whereby an attraction is set up between different molecules. On union of two such molecules the new molecule of double size, or double size less a molecule of H_2O, possesses also two free and opposite poles; so that under favourable conditions a repetition of the chemical union described may proceed and that without limit, save the stability of the chemical system, until an equilibrium between the anabolic or synthesising and catabolic or disrupting forces is attained. Change the

environment of the cell and the limiting conditions change. There are all possible gradations in the degree of such unions: it has become customary to speak of the feebler unions as adsorptions. In the state of present knowledge it is impossible to say whether certain unions are physical or chemical—it may one day appear that there is no fundamental difference between the two types of union. The fact remains that certain unions are only stable so long as a certain concentration or pressure is maintained, and break up as the pressure diminishes.

The cells of the body are rich in potassium and phosphatic ions and poor in sodium and chlorides. The fluids, on the other hand, are rich in sodium and chlorides and poor in potassium and phosphatic ions. It would appear, therefore, that the tissue cells have special chemical affinities for potassium and phosphatic ions, and no such affinities for sodium and chlorine. The proteins of the fluids apparently possess the opposite affinities. The view is held to-day that the chief factors determining equilibrium between ion and cell are concentration of ion and the affinity (adsorptive or chemical) between the ion and the cell. This affinity changes its value from one ion to another in the same cell, and from one cell to another with the same ion.

That ions are in a loose type of union with proteins is evident when we consider that depression of the freezing-point in blood serum is almost the same as in water containing an equal amount of salts; the same remarks pertain to the electrical conductivity in the two cases.

It was formerly thought that if there were sufficient quantities of proteins, carbohydrates and fats in the diet, health was ensured. With lapse of time, quality of food as well as quantity attracted attention.

We now know that the quality factor is all-important. We have seen that proteins deficient in aromatic amino-acids, such as tyrosine and tryptophane, fail as nutritives. No excess of other amino-acids will meet this deficiency.

With some knowledge of the properties of internal secretions, hormones, and enzymes of various types, we are prepared to accept the view that the presence or absence of the merest trace of an active biochemical substance may be the cause of effects profoundly beneficial or disastrous.

Attention has been focused in recent years on certain conditions described as deficiency diseases: Beri-beri, pellagra, scurvy, rickets, etc. It has long been known that the Tamils in the Malay Peninsula who consume unpolished rice do not suffer from beri-beri. Other races who suffer from the disease use their rice in such ways that it is not clear whether the disease is wholly due to the lack of the polishings. Considerable experimental work has been done on animals, especially birds, with a view to clearing up the position. Pigeons and chickens fed on polished rice become victims of the disease. The same birds fed on unpolished rice escape. If taken in time, the disease may be stopped by adding to the diet of unpolished grain the polishings or a chemical preparation of the polishings. Funk has attempted to recover chemically the substance or substances (named by him, vitamines) which prevent the neuritic condition in animals; but, so far, no definite body has been isolated. A large number of substances generally employed as foodstuffs are said to contain vitamines, *e.g.*, extracts of yeast, wheat, barley, oats, maize, beans, milk, cabbage, wholemeal bread, bran, etc. Such bodies are said to be soluble in alcohol and water, to be able to pass through a semi-permeable membrane, and to be destroyed at a temperature of 100°. It has been thought that they correspond with certain pyrimidine compounds, and some one has ventured the opinion that they are identical with allantoine or one of its derivatives.

Abderhalden and Lampe found that boiling the rice—thereby presumably weakening or killing the toxin—diminished its power to produce polyneuritis, but did not prevent it altogether.

In pellagra, cure can often be effected by replacing the maize by other cereals.

In scurvy, cure is rapidly produced by the administration of lemon juice, green fresh vegetables, etc. An exclusive diet of bread produces scurvy in guinea pigs, rabbits, dogs and pigs (Holst and Frolich). Heat and long keeping are said to decompose the antiscorbutic substance. Many antineuritic foods, such as yeasts, barley, oats, etc., contain no anti-scurvy vitamine.

Rickets is now known not to be due to lack of fat nor lime salts. Hopkins' experiments on young rats (*Jour. Physiol.* XLIV. 1912) points to something of the nature of vitamine in minimal quantities of fresh milk which can prevent scurvy. Osborne and Mendel have located a growth-vitamine in the fat of milk, and have demonstrated the failure of lard to promote growth in the same manner as other natural fats do (butter fat, egg yolk, cod-liver

oil, etc.). This failure is shown not to be attributable to deteriorating changes arising from heat or chemical agents in the manufacture of the product. They show that heating butter fat with steam does not destroy its growth-promoting efficiency. Beef fat is more efficient in promoting growth than lard. When butter fat and beef fat are fractionally crystallised from alcohol, the growth-promoting factor remains in the mother liquor or "oil" fractions. The fractions containing fats with high melting-points are ineffective.

A recent paper by W. L. Braddon and E. A. Cooper shows that chickens fed on one-twentieth their body weight daily of parboiled unpolished rice, or fresh partly polished rice, remain free from polyneuritis for twenty-eight to one hundred days. Chickens fed on the same ration of polished Siam rice develop symptoms of polyneuritis in twenty to seventy days.

When polished rice is soaked in excess of water for twenty-four hours, the birds succumb to polyneuritis in from ten to thirty-five days; when the rice is soaked for forty-eight hours the disease appears still more readily, viz., in fifteen days.

Chickens fed on one-twentieth their body weight of parboiled rice, which had been soaked for twenty-four hours, also develop polyneuritis in from thirteen to thirty-nine days. This fact is regarded as of practical importance, since epidemics of beri-beri have been traced to the practice of soaking unpolished rice prior to cooking and discarding the water.

Although birds fed on diets of polished rice, sago, or glucose, develop polyneuritis, when fed on commercial starch they fail to do so, and merely lose considerably in weight. While fowls fed on one-twentieth their body weight of parboiled unpolished rice remain free from polyneuritis for at least sixty to one hundred days, when this ration is supplemented by one-sixth the body weight of washed unpolished rice, they develop polyneuritis in about the same time--ten to twenty days.

On dietaries composed of rations of polished rice, varying from one-twentieth to one-fortieth the body weight, and of yeast varying from $\frac{1}{2500}$ to $\frac{1}{3500}$ the body weight, pigeons and chickens do not develop polyneuritis until at least thirty-two to one hundred days have elapsed; but when the carbohydrate ration is doubled by the addition of polished rice or sago the birds fall ill in from thirteen to forty-six days.

When daily rations of polished rice as large as one-tenth the body weight are fed to chickens, together with varying amounts of yeast, 93 to 98 per cent. of the carbohydrate is digested and absorbed, and the excreta contain no anti-neuritic substance. This shows that the rapid development of polyneuritis induced by feeding large rations of starch is not due to interference of undigested carbohydrate with the absorption of the active material. Intestinal bacteria, unlike yeast, contain little anti-neuritic substance. These observers conclude that the amount of anti-neuritic substance required by the organism increases with the quantity of carbohydrate metabolised. For the maintenance of health the intake of active substance must, therefore, be adjusted so as to stand in some quantitative relation to the ration of carbohydrate ingested, and it is when this necessary balance is not maintained in the dietary that beri-beri results. Although as ordinarily induced beri-beri can be described not inaccurately as a deficiency disease, it may thus actually develop when a dietary containing an adequate amount of the anti-neuritic substance is regularly supplemented by a ration of a carbohydrate foodstuff deficient in this essential substance. Attention must therefore be paid to the proportion which the anti-neuritic foodstuff bears to the total carbohydrate ration. Large rations of those foodstuffs deficient in the essential substance should be avoided. In a dietary intended to prevent beri-beri, it is necessary to consider both the content of the anti-neuritic material and the total calorific value.

Sperry and Rettger having thoroughly purified the proteins, egg albumin, serum albumin, and edestin, demonstrated that the following bacteria, aerobes and facultative anaerobes, viz., B. subtilis, B. anthracis, B. pyocyaneus, B. prodigiosus, B. proteus vulgaris, B. coli communis, B. typhosus, and S. pyogenes aureus, are unable to attack these native proteins in the pure state. They extended their research to three anaerobes, viz., B. putrificus, B. anthracis symptomatici, and B. oedematis maligni, and found the action of these to be also negative. Solutions of native proteins may undergo complete proteolysis, if they contain peptone or other nitrogenous food material, which readily furnishes the nitrogen necessary for bacterial development. In such cases the proteolysis of the native protein is the immediate result of the action of an enzyme, which has been elaborated by the bacteria during the process of rapid multiplication. This

multiplication is made possible by the N-containing material present along with the native protein. The molecule of the native protein apparently must be split by a cleavage agent, such as an enzyme, acids or alkalies, heat, etc., before the bacteria can utilise it.

It is impossible to avoid the entrance of bacteria into the digestive tract. The normal flora of the alimentary tract, the obligate bacteria as they are sometimes called, *e.g.*, B. lactis aerogenes, B. coli, B. bifidus, have adapted themselves to the secretions, and by virtue of their adaptation, hold their own against new-comers. The common foodstuffs are liable to contain injurious bacteria, such as pyogenic cocci, typhoid, paratyphoid, and dysentery bacilli, B. proteus vulgaris, and the sporing anaerobes B. putrificus, B. aerogenes capsulatus, and B. botulinus. The proteolytic action of pepsin and trypsin in healthy individuals acts as an effective check to the growth of most varieties of bacteria.

The members of the B. lactis aerogenes group are morphologically little different from those of the B. coli group. Greater differences exist in their biochemical characters. They form gas on sugar media more readily, coagulate milk more rapidly, produce gas from potato starch, and fail more frequently to manufacture indole. Their fermentative powers are greater than those of B. coli, whilst their putrefactive powers are less.

Few living bacteria of the B. coli group are present in the fæces of healthy persons with obstinate constipation. Certain bacteria have the power of checking the growth of B. coli. Streptococci from human fæces repress the growth of B. coli in the anaerobic limb of the fermentation tube.

B. coli exerts an inhibitory action on the putrefactive anaerobes, so also does the B. bifidus group. The presence in the colon of immense numbers of obligate bacteria of the B. coli type may be an important defence against putrefactive decomposition.

If one places some fæcal matter from a healthy breast-fed infant in a closed test tube in an incubator, the original not disagreeable odour lasts for days or weeks. Indeed, it is possible to inoculate such material with B. putrificus in quantity and obtain no evidence of putrefaction. The stools of such a normal infant exert an intense inhibitory action against various bacteria. The inhibitory substances to which the restraining effect is attributed appear to be less active in the stools of nurslings than in those of adults.

If mixed fæcal flora be grown in sugar broth, and in sugar broth containing $CaCO_3$, for a week at 37°, it will be found that a considerable quantity of volatile fatty acids has been formed in each case. The quantity will be considerably greater in the carbonate flask. The molecular weights of the acids found in the carbonate broth are higher than those of the acids in the sugar broth. This suggests a greater activity of putrefactive bacteria in the neutral medium, for such tend to form the higher rather than the lower fatty acids. A neutral medium favours the development of putrefactive bacteria, especially of the anaerobes; an acid medium restrains the growth of putrefactive bacteria and encourages the growth of lactic acid producers. In the neutral flasks some of the lactic acid is probably transformed into butyric acid. The influence of milk containing lactic-acid formers in controlling putrefactive decompositions in the digestive tract finds its explanation in the inhibitory action exerted by these bacteria and by the lactic acid already formed. The chemical character of the food, the solubility of the food in the digestive juices, the quantity and composition of these digestive juices, all affect in important ways the ultimate fate of the food in its relation to bacterial decomposition; and intimately connected with these factors is the influence of aerobic and anaerobic conditions of the tube.

By the careful application of Gram's stain, it is possible to divide all the bacteria found at a given level of the bowel into two groups—those which retain the stain, Gram-positive, and those which do not retain the stain and are hence susceptible to colouration by a counter stain, Gram-negative. This difference of behaviour is due to biochemical differences in the bacteria. If this method of examination be supplemented by making aerobic and anaerobic cultures on plates of various media, one obtains a fairly accurate idea of the representative bacteria of the tract.

Suspensions of fæcal material in the proportion of one part by weight to ten parts of normal saline solution are prepared and used to make smears on microscopic slides. When dry and fixed, the smears are stained by Gram's solution for a period of about three minutes. The solution is run off the slide, not washed off, and Lugol's iodine solution is applied for two minutes. The slide is then rinsed with water and decolorised for half a minute with absolute alcohol. Lastly the smear is counterstained with a dilute fuchsin solution. The same technique must always be applied, otherwise confusing results are obtained.

A smear thus prepared from a healthy breast-fed infant's fæcal matter presents a characteristic field. The bulk of the bacteria are Gram-positive, and present the appearance of a nearly pure culture of one type. The organisms are slender bacilli slightly curved and of moderate size; they are the B. bifidus of Tissier. This organism dominates the field. Perhaps there are a few large plump bacilli occurring singly or in pairs, the B. aerogenes capsulatus, and a small number of Gram-positive diplococci growing in chains. The principal remaining Gram-negative bacteria are the B. lactis aerogenes and B. coli.

In the case of infants fed on cow's milk, the picture is different; the number of bacteria is considerably greater. The dominant organisms are of the B. coli type. The field, in other words, is as a whole Gram negative instead of Gram-positive. In adults the number of putrefactive anaerobes is larger. The presence of B. aerogenes capsulatus can be determined by anaerobic plating in blood agar. B. putrificus may also be present. B. coli is well represented.

In old age the putrefactive organisms are still more abundant.

The intestines of carnivorous animals contain many more putrefactive organisms than those of the herbivorous. Inoculations in bouillon flasks produce sulphuretted hydrogen and methyl mercaptan. Colonies on anaerobic plates show that a large portion of the organisms are B. aerogenes capsulatus. A generous use of meat in the human subject over a long period of time encourages the development of much larger numbers of spore-bearing anaerobes than would be the case if a different type of protein were substituted for meat.

It is known that the fresh tissues of animals reduce methylene blue; and the reducing action of fresh liver has been utilised in the anaerobic arm of the fermentation tube. Meat that has been but slightly cooked retains a considerable portion of its reducing power. These facts have their application in the alkaline fermentation found in the lower bowel of large meat eaters.

Prompt absorption of food, more especially protein food, is one of the most important factors in preventing the occurrence of excessive putrefactive conditions in the alimentary canal. The presence of large quantities of partially-digested proteins in the anaerobic region of the gut facilitates putrefactive fermentation. Those measures which are designed to secure prompt digestion and prompt absorption limit to the greatest degree putrefactive decomposition.

Since different types of bacteria possess their own special forms of foodstuffs, and disappear when the foodstuffs necessary for existence disappear, it is quite possible, by changing as radically as circumstances will allow the entire dietary at times, largely to compel the disappearance of certain organisms. The treatment of putrefactive fermentations on these lines has been successful.

From the Gram stain one learns something of the number of colon bacilli, of the state of their preservation, of the number of Gram-positive diplococci, of the presence of B. bifidus, and of the number of sporing anaerobes. Further, the method is useful in studying the sediments in fermentation tubes inoculated with mixed fæcal flora. In tubes inoculated from normal persons Gram negative organisms, corresponding in size and form to B. coli, grow abundantly in all the tubes. These are accompanied by Gram-positive and Gram-negative diplococci in moderate numbers, and by very moderate numbers of B. aerogenes capsulatus.

In cases of excessive intestinal putrefaction B. putrificus is found in abundance in bouillon flasks neutralised by $CaCO_3$. Such flasks may contain H_2S, methyl mercaptan, ammonia, volatile fatty acids, indole, phenol, and skatole. If methyl mercaptan is shaken with isatin-sulphuric acid the red changes to deep green.

Two molecules of indole unite with one molecule of β-naphtha-quinone-sodium-mono-sulphonate in the presence of a small quantity of alkali to produce a blue or greenish blue colour. A concentrated solution of indole will give a precipitate. By this means indole can be removed from a mixture of indole and skatole. The last can be distilled and recognised by the blue colour produced with Ehrlich's aldehyde, dimethyl-amido-benzaldehyde.

Bienstock's B. putrificus is a spore-bearing strict anaerobe, giving rise to characteristic products of putrefaction, including butyric acid and hydrogen. It forms H_2S and methyl mercaptan, but not indole.

B. aerogenes capsulatus is a strict anaerobe difficultly spore-bearing, gas-forming, and Gram-positive. The gas consists of CO_2 and H. This organism contains hæmolysing and proteoclastic enzymes, and forms butyric acid.

Propionic, butyric, and higher volatile fatty acids are common products of putrefaction. They are formed by putrefactive anaerobes, not only from protein media, but also from sugar-containing media.

During putrefaction ammonia and other bases

appear. Phenols, cresols, skatole, and indole may all be found in the same putrefactive digest, and in the faeces of patients suffering from intestinal putrefaction. Herter showed that the hepatic and renal cells and the epithelial cells of the intestinal tract can absorb considerable quantities of indole and phenol, tying them loosely so that they cannot be recovered by distillation. This action, he held, served as a screen to the nervous system. Their presence, even in slight concentration in the blood, induces violent nervous excitation followed by depression. Where the intestinal and liver cells are damaged, and the screen accordingly destroyed, the worst symptoms of autointoxication appear. Free indole circulating in the blood induces severe muscular fatigue.

Intestinal indicanuria is an evidence of intestinal putrefaction. It is easily produced in dogs by feeding excessive quantities of meat.

In certain cases of indicanuria of high degree ferric sulphate has been beneficially administered as a catalyser, inasmuch as small quantities of this salt render some oxidations of organic matter much more efficient.

When certain individuals of middle age or over consume excessive quantities of proteins—*i.e.*, larger quantities than they can assimilate and finally oxidise—a more or less definite set of symptoms appears, characterised by headache, drowsiness, lassitude, and irritability. Such symptoms are accompanied by abnormal physical and chemical changes in the urine, by physical, chemical, and bacteriological changes in the fæces, and by increased arterial tension The urine of such a patient is more toxic to animals than normal urine; its surface tension is lowered; it contains increased quantities of indole, indole-acetic acid, phenol, skatole, and aromatic oxyacids—all products of intestinal putrefaction. The ratio of ethereal to preformed sulphates is increased. The ratio of ethereal sulphates to total nitrogen is increased. It is known that chlorides, phosphates, sulphates, etc., raise the surface tension of urine, that other bodies, such as urea, sugar, and albumin, act indifferently; whilst aromatic compounds and certain fatty acids depress it. The curve of surface tension runs parallel with the curve of aromatic constituents. The quantity of urine is variable; frequently it is less than normal. The specific gravity is variable; not infrequently it is less than normal. The fæces may be solid and dry or diarrhœic, or alternate between constipation and diarrhœa. The odour may be highly offensive. Undigested proteins, fats, and carbohydrates are present in varying quantities. A carefully prepared 10 per cent. suspension in normal saline examined microscopically by Gram's method yields a field in which the dominant organisms are B. aerogenes capsulatus and B. putrificus; whereas a corresponding preparation from the fæces of a patient of the same age in perfect health furnishes a field in which the dominant organism is B. coli. The chemical reaction is alkaline. Phenols may be recovered from the liver of such a patient should he die suddenly by accident. Is there a causal relationship between the phenols of the fæces of this patient and his clinical condition? I think there is.

It will be objected that the evidence deduced from experiments on animals is not sufficient to show that the indoles and other aromatic bodies are toxic. It will be further objected that individuals can be found who excrete large quantities of indoles and other aromatic bodies conjugated with sulphuric and glycuronic acids, and yet have no toxic symptoms. These individuals, I reply, completely oxidise their phenols. That the phenols and other aromatic bodies mentioned are produced by the hydrolysis of proteins by anaerobic bacteria must be admitted. These products do not occur in the fæces or urine of the healthy breast-fed infant, whose alimentary tract is free from putrefactive anaerobes. They occur only in small quantities in the healthy adult. In adults in whom they occur in larger quantities, and who suffer from toxic symptoms, they can be greatly lessened and made to disappear by substituting carbohydrates for proteins in the diet. The toxic symptoms decrease and disappear at the same time. In this, as in all other problems of metabolism, the most important matter for consideration is not what happens in the alimentary canal, nor what bodies are found in the urine, but what is constantly happening in the body tissues—blood, liver, cord, brain, etc. This patient suffers because he is unable to oxidise sufficiently the aromatic bodies formed in his large bowel by the action of anaerobic bacteria on proteins. Perhaps the epithelial cells of his intestinal mucosa are damaged and fail in their antitoxic action; or, being damaged, they let through more toxic material than the other portions of the oxidising machinery (hepatic cells, cells of the thyroid, suprarenals, etc.) can deal with. Or it may be that other parts of the oxidising machinery are at fault.

The statement that dogs and monkeys have been injected with indoles and phenols and have

failed to show any symptoms of toxaemia in no way militates against the other statement that such products damage certain men. The oxidising powers of the dogs for these substances are greater than those of the men. The dogs can deal efficiently with the toxins, hence no toxaemia. The quantity of aromatic bodies in the fæces furnishes no information concerning the work that is being done by the oxidising machinery. The latter can only be measured imperfectly by the aromatic sulphates and salts of glycuronic acid in the urine. On substitution of carbohydrates for proteins in the diet of such cases the ethereal sulphates gradually diminish. That they do not fall suddenly in many cases points to the conclusion that oxidation goes on in the tissues after putrefaction has ceased in the gut. Such inability on the part of the oxidising machinery to keep pace with the formation of putrefactive products is a definite indication for the reduction of protein in the diet. In the treatment of this form of auto-intoxication animal proteins may be discarded entirely for a time as they yield larger quantities of phenols than vegetable proteins.

It will be clear that the resolution of problems of this kind, as indeed most problems in practical medicine, can only be satisfactorily effected by a balanced combination of clinical and laboratory research. And perhaps it will be one day admitted that the widest and soundest knowledge of such natural phenomena can be obtained only by those who cultivate both fields of research.

WINTER OATS.*

While endeavouring to increase the area under wheat, farmers should arrange, if possible, not to reduce the area under oats, for, to a nation at war, this grain may be just as useful as wheat, and the straw is of special value as fodder for stock. In many districts, particularly in the south of England, repeated attacks by frit-fly (sometimes called "bottling") have rendered spring oats a precarious crop. Winter-sown oats, however, are less liable to attack by this pest, and might, therefore, receive increased attention at the present time. They are also better adapted than spring oats for land badly infested with charlock.

Varieties of Winter Oats.

Two varieties are commonly grown, namely, Winter Grey or Dun Oat, and Winter Black Oat. In deciding which to grow farmers should be guided largely by local experience, for while both may grow equally well in any particular district, there is sometimes a keener local demand by merchants for one than for the other. The black variety possesses somewhat stronger straw than the grey, and might generally be given the preference on land subject to "lodging." It is more liable to shed its seed than the grey variety, and should be cut before it is dead ripe. In neither case is the straw so palatable as that of the finer spring varieties, but when chaffed and mixed with cake and meal it is readily eaten by stock.

* Special leaflet issued by the Board of Agriculture and Fisheries.

Soil and Cultivation

Winter oats are suited to a wide range of soils. They can be grown successfully on soils too light or too poor for wheat, and they prevent such soils from "washing" in a wet winter. Further, they can be taken as a second corn crop, provided the land is clean. They are not so hardy as winter wheat or winter barley, and consequently must be sown earlier, preferably in September, so that the plants may become well established before cold weather sets in. The ground should be left somewhat rough as a protection against cold winds; and with this object in view it is customary in some districts not to harrow after drilling.

Unless the land is thoroughly clean, weeds, favoured by a longer growing period than usual, may seriously reduce the crop.

About three to four bushels per acre should be sown; the earlier the sowing and the cleaner the land the less the quantity of seed necessary.

Winter oats often contain seeds of a Brome Grass (*Bromus secalinus*), a troublesome weed on light land; purchasers should see that seed oats have been carefully cleaned.

Winter oats are best suited to the warmer southern counties, and are generally ready for cutting from ten days to a fortnight before other corn crops. This enables the land to be prepared sooner for the following crop, a point of some importance when farming is conducted at high pressure. On the other hand, the earlier ripening is a disadvantage near towns where birds are numerous.

SILK AND SILKWORM INDUSTRY IN CHINA.

The China number of the *Manchester Guardian* contains an interesting account of the Chinese silkworm industry.

Hatching and Feeding

The cocoons selected for the following year's breeding are suspended and threaded through the loose web with string and hung in a dark place, where the worm, which has formed itself into a chrysalis, lives during its confinement; then, as a moth, in about eighteen days it bites its way out of the cocoon. The moths are then placed on sheets of brown paper about eight inches square and allowed to pair off, and after about four hours they are separated, the females remaining on the paper (covered over with a rice basin). In

about twenty-four hours four moths will lay between five and six hundred eggs, the eggs adhering to the papers. These papers are sold at 20 cents a sheet or stored in boxes until next breeding season (20 cents are equal to *5d.*). The cocoons which the moths have left are called pearced. The loose web which is taken off the cocoon before spinning is called strippings. Both are refuse silk and are exported to Europe, made up into various articles, such as silk and cotton rugs, etc., reimported into China, and exported to other countries. In the month of April the hatching season begins, and if the first brood is strong and healthy two crops will be obtained in one season.

The first process is done by the native women placing the sheets of paper on their breasts next to the skin, and keeping them there day and night until the silkworms begin to hatch out as little dark objects. The papers are then placed on cotton wool in order to retain the heat from the body, and the silkworms are fed on finely chopped mulberry leaves. Then they are allowed to rest and not fed until a movement is seen; then fed again, and then given another rest. This is repeated several times. The worms grow very quickly, and when strong enough are removed to round bamboo trays and fed, the whole mulberry leaves being placed lightly on top of them. They are then fed every four hours night and day, and occasionally changed to clean trays.

Stripping and Spinning.

In about four weeks they have grown wonderfully, and if proper care has been taken of them they are ready to spin, which is noted by their throwing their heads up and refusing to eat, the threads of silk being now seen between their feet. They are then removed to rice straw on round trays, on which they wander until they find a suitable place to spin the cocoon. If kept a little in the dark during all stages they will work quickly and thrive much better. In a few days they will all have enclosed themselves in cocoons. It is very pretty to see the straw all covered with these egg-shaped silk balls, yellow and white intermixed. When they have all spun and the cocoons are hard to the touch they are taken from the straw. The loose web is stripped off the cocoon, placed on round trays and dried in the sun for a few hours, and taken to the spinning-wheel, a crude affair consisting of a wooden wheel on two uprights. Another stand holds an earthenware charcoal shatty and an iron pan (like that in which the natives boil their rice) in a wooden upright. There is also a contrivance with three arms. Between the two upper ones is a bamboo roller; the lower arm bears a copper cash. Fresh water is placed in the pan and kept up to nearly boiling-point, about twenty cocoons are placed in the hot water, and, with the assistance of a pair of chopsticks, the threads are picked up together, passed through the square hole in the copper cash, once round the bamboo roller, and over to the spinning-wheel. Each cocoon gives off one thread of silk; so many of these are brought together in the spinning, and every bit of silk is wound off each, leaving the chrysalis bare.

The natives do not like to destroy the moths on the premises after breeding for fear of spoiling their hopes of a good crop next year; so small boats are made from bamboo leaves in which they are placed and floated down the stream. Now the silk all spun, in its two natural colours, yellow and white, is taken to the dyeworks and then to the hand-loom, which is another cumbersome wooden structure taking up the space of no less than 20 ft. by 6 ft. by 9 ft. Each machine is worked by a man and a boy, various lengths and widths are made, figured, plain, or raised velvet figured, according to requirements; it is all hand work, and one machine will make from one and a half to two yards a day. Many of the owners of these looms sell the silk off the loom either by native measure or by weight.

Mulberry Culture.

The mulberry tree is cultivated in this part of the country, not for the fruit, but for feeding the silkworm, and miles of these trees can be seen in perfect lines well looked after.

TRADE AND COMMERCE OF BENGASI FOR 1913.

Bengasi, on the Tripoli coast, was occupied by the Italians on October 20th, 1911, and although a new era was thereby introduced in the history of the country, the protracted resistance of the Beduin tribes which has thereon ensued has hindered the development expected. Trade with the hinterland has been checked, capital has held aloof, settlers are not attracted, and even the most necessary public works are proceeding slowly. In spite of an exceptionally plentiful rainfall, only a small quantity of grain has been realised; the crop in the more distant parts of the province has been gathered by the Beduins. For two years after the occupation the military operations prevented any sowing, and the exportation of grain is still prohibited. The imports of wool and butter have fallen off considerably, and the trade in ivory and ostrich feathers from Wadai has, for the present, ceased entirely. In spite, however, of these discouraging circumstances, the imports into Bengasi have already recovered the level of former years, and appear to be steadily increasing; and in flour, meal, vegetables, groceries, wine, beer, hardware, soap, and coal the increase has been very considerable. Although the information is as yet only roughly classified, there is enough to show that Italy has now a very strong position in the trade of this port, while other countries remain a long way behind. The principal cause of the growth of Italian trade here is the presence of the army of occupation, and of a large and increasing element in the town population.

Regular steamship services, and direct postal and telegraphic communication with Italy, the presence of branches of the Bank of Italy and of the Bank of Rome, all help to consolidate Italian influence and commercial supremacy in the district. The only regular lines are the Italian, Sicilia and Servizi Marittimi, the Hungarian Adria, and the German Levant Line. No British ship called in 1914, and in 1913 only two put in, one of them bringing a cargo of coal for the railway.

Plans for the construction of a harbour, large and deep enough for the accommodation of steamers that now have to lie out in the open roadstead, have been prepared by the public works department of the Italian Government. It is proposed that a shallow place, enclosed by a reef facing the town, should be filled in and converted into quays. Beyond the reef, where there is a depth of 46 ft., two piers or breakwaters would be built to form a spacious basin. The cost is estimated at thirty million lire, or £1,200,000, and the work would take about eight years to complete. A Decanville railway interconnects the forts outside the town and runs out a few miles to Benina, this being probably the first step towards the ultimate connection which will be established with Egypt by rail.

One great drawback to the development of the country is the scarcity of water. A good rainfall, such as that of 1913, means abundance, while the bad years, which unfortunately are more frequent, may bring the inhabitants to the verge of starvation. The necessary works have not yet been completed. Water is still brought into the town in small barrels carried by diminutive donkeys, though water-carts are also beginning to be used. Additional wells have been sunk, pumps and tanks have been erected, and pipes have since been laid to carry the water to the town. The dust, the glare, the swarms of flies, and the usual Oriental neglect of rational hygiene cause a distressingly high percentage of blindness and ophthalmia, while coloured goggles and glasses are extensively used by both Europeans and natives.

THE FORESTS OF FRANCE.

As regards the extent of her forests, France occupies the sixth place amongst the countries of Europe, following, in order of importance, Russia, Sweden, Austria-Hungary, Finland, and Germany. The forests of France cover an area of 886,701 hectares (3,423 square miles).

In proportion to its size the Department of the Landes contains the largest area of forest, the greater part of which is due to the replanting of the uncultivated lands, and now occupies more than half, or 55·4 per cent., of its total surface. The woods in the Departments of the Var cover 49·5 per cent., and in the Gironde 46·2 per cent. The smallest proportions of forest lands are in the Departments of Finisterre, 4·4 per cent.; Seine, 8·7 per cent.; and the Manche, only 3·2 per cent. The mountainous regions are less wooded than is popularly supposed, Savoie, 22·4 per cent.; Haute Savoie, 28·4 per cent.; and the Vosges, 36·9 per cent., in all of which Departments it is very desirable that the example set in the Landes in the replanting of forest trees should be followed.

The largest forest in France is that of Orleans, which covers an area of 30,000 hectares (116 square miles). The forest of Fontainebleau, probably the most beautiful in France, has an area of between 15,000 and 17,000 hectares (about 58 to 65 square miles). Its picturesque glades, alleys, and gorges are much frequented by artists and lovers of forest scenery during the summer.

Amongst others famous for their beauty may be noted those of Pontarlier, Eu, and especially the forest of Tronçais in the Department of Allier, which covers an area of 10,000 hectares (38 square miles). The forests of the Ardennes and Compiègne are noted for the chase.

The timber grown in these forests is principally oak, birch, pine, beech, elm, and the Spanish chestnut, whilst the cork tree flourishes in the south of France, especially in the Department of the Var.

VETERINARY WORK IN INDIA.

Considerable progress has recently been made by the Provincial Veterinary Departments of India in educating the people to believe in the scientific treatment of animal diseases. The numbers of cases treated in hospitals and dispensaries, and by officers on tour, are steadily increasing, and in one province, the Punjab, many private individuals have come forward to establish veterinary hospitals at their own expense, while in the Central Provinces some of the cattle-owners voluntarily deposited the cost of 500 doses of anti-rinderpest serum. At first there was strong prejudice against inoculation, but, according to the Report on the Progress of Agriculture in India for 1913-14, cattle-owners are beginning to look upon it with great favour, and consider it the only satisfactory measure to be adopted against rinderpest. Striking instances of the efficacy of the anti-rinderpest serum were demonstrated at Gaisabad and Chanda in the Central Provinces, where 7,233 cattle were inoculated with no mortality amongst them.

In some of the provinces rinderpest was more widespread than in previous years, and there would have been a great increase in the number of animals inoculated but for an unfortunate breakdown in the supply of serum from Muktesar. Large orders for the serum were received from Egypt, the Sudan, and Rhodesia, which had to be set aside; but new centrifuges have been installed at the Imperial Bacteriological Laboratory at Muktesar, and a branch laboratory at Bareilly is being expanded, by which it is hoped that it will be possible to meet the growing demand for serum.

Special endeavours have been made to improve

the sheep industry in the Punjab. Breeding experiments, undertaken in the United Provinces with a view to ascertain how far the fleece of the indigenous sheep can be improved, have so far yielded satisfactory results. The introduction of a merino cross has produced a very beneficial effect on both the quality and quantity of the fleece. Similar experiments have also been conducted at Pusa.

A good deal of useful research work has also been carried out at the Muktesar laboratory and also by individual officers of the provincial departments in connection with rinderpest, surra, anthrax, kumri, and bursati. The Imperial pathological entomologist at Pusa has continued his investigations on the bionomics of flies likely to be surra carriers, on the habits and life-history of lice, and on the egg-laying reactions of blood-sucking *muscidæ*.

CORRESPONDENCE.

NON-POROUS ALUNDUM FOR PROTECTING SHEATHS OF PYROMETERS.

In the course of my paper on "Recent Progress in Pyrometry," read before the Society on May 12th last, the following passage occurs (*Journal* of May 14th, 1915, pp. 593 and 594).—

"Several new materials have been introduced to form the protecting sheaths necessary to shield junctions from the corrosive action of furnace gases. Alundum (oxide of aluminium) is now used for this purpose; but, although it possesses a high melting-point (2050° C.), it is too permeable to gases, particularly at high temperatures, to be of general service."

Since the paper was written I have been informed by Messrs. Townson and Mercer, the British agents for alundum, that a non-porous variety can now be obtained, suitable for pyrometer sheaths, etc., the refractory qualities being equal to those possessed by the ordinary kind. Experiments with various gases show that the new material is not permeable even at temperatures exceeding 1400° C., and hence forms an efficient shield for pyrometer wires or materials which would be deleteriously affected by furnace gases.

CHAS. R. DARLING.

GENERAL NOTES.

ENGINEERING CONGRESS AT SAN FRANCISCO.—An international engineering congress was held last week at San Francisco. A large number of the papers read dealt with various engineering aspects of the Panama Canal, and the congress was appropriately presided over by Colonel Goethals. Among the British contributors were Sir Albert Stanley, who presented a paper on "London Traffic in 1913"; Mr. Alfred Dryland, county surveyor of Surrey, on "The Construction and Maintenance of Rural Highways"—a subject which was also dealt with by Mr. Arthur Gladwell, surveyor to the Eton Rural District Council. A short paper on "Public Utilities" was contributed by Mr. Edward Willis, of Chiswick; whilst "Testing of Materials" formed the subject of a paper by Mr. R. G. Batson, of the National Physical Laboratory. A Sheffield engineer, Mr. A. J. Capron, dealt with "Recent Progress and Present Status of the Art of Forging, with special reference to the Use of Quick-acting Forging Presses." In the electrical engineering section there were two contributions by English authors—one by Dr. H. F. Marshall, of London, on "The Economics of Electric Power Station Design," and the other on "The Production of High Permeability in Iron," by Professor Ernest Wilson, of the University of London, King's College.

"THE ENGLISHWOMAN" EXHIBITION OF ARTS AND HANDICRAFTS.—This exhibition will be held at the Central Hall, Westminster, from November 17th to 27th. There will be exhibits of hand-weaving, jewellery, pewter, leatherwork, book-binding, pottery, sculpture, stained glass, enamelled glass, woodcarving, inlaid furniture, Chinese lacquer, antiques, artistic dress, handmade flowers, embroidery, lace, baskets, dressed dolls, toys, illumination and caligraphy, illustrations, colour printing, etching, water colours, miniatures, photography, gardening, lingerie, children's and ladies' frocks, smocks, etc. Owing to the war, workers in arts and handicrafts have received very little support from their usual clients during the year, and depend largely for their opportunity of sales upon such exhibitions as the one to be held at the Central Hall. Further particulars may be obtained on application to the Secretary, *The Englishwoman*, 11, Haymarket. S.W.

PROPOSED WAR EXHIBITION AT LIÉGE.—It is proposed by "L'Oeuvre des Artistes," an Art Society of Liége, to organise a great war exhibition, as soon as the liberation of Belgium is effected. The exhibits will include, among other things, pictures, engravings, lithographs, and war posters.

CHADWICK LECTURES.—The third programme of War Lectures, under the Chadwick Trust, will be given as follows: Professor D. Noel Paton will lecture on "Food in Wartime," at the Hampstead Central Library, on October 4th, 11th and 18th, at 8.15 p.m; Dr. R. O. Moon will lecture on "Typhus in Serbia," at the Royal Society of Medicine, on October 20th and 29th, and November 3rd, at 5.15 p.m.; Mr. A. Saxon Snell will lecture on "Emergency Military Hospital Construction," at the Royal Institute of British Architects, on November 10th, at 8.15 p.m.; and Mr. W. E. Riley on "Some Conclusions on Housing our Workers," at the Royal Sanitary Institute, on November 17th, at 8.15 p.m.

Journal of the Royal Society of Arts.

No. 3,281. VOL. LXIII.

FRIDAY, OCTOBER 8, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

MUNITIONS INVENTIONS DEPARTMENT.

The Secretary of the Royal Society of Arts has received the following communication from the Comptroller of Munitions Inventions:

Princes Street.
Westminster, S.W.
October 4th, 1915.

The Secretary, Royal Society of Arts.

SIR.—Permit me, through you, to draw the attention of the members of your Society to the fact that the Munitions Inventions Department, which, you will remember, was recently constituted by the Minister of Munitions for the purpose of dealing with ideas, suggestions, and inventions for appliances in connection with the prosecution of warfare on land, has been authorised by him to receive projects of this nature on any matters appertaining thereto.

An advisory panel of scientific and other experts, appointed by the Minister, is assisting the Department in the task of dealing with the large number of inventions that have been, and are being, received, every one of which is given consideration by the panel. This body is glad to consider also suggestions with regard to simplification and improvements either in the manufacture or in the materials of existing munitions, or, indeed, in any other respect.

I should be glad if you would make known as widely as possible to your members our existence and functions.

I am, Sir,
Your obedient servant.
E. W. MOIR,
Comptroller of Munitions Inventions.

CANTOR LECTURES.

The Cantor Lectures on "Oils, their Production and Manufacture," by F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.T., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London W.C.

ORGANISATION.*

This, I venture to think, is by far the most important question of any I have raised, and I will go so far as to say that I believe it to be the all-important one, as it practically embraces the others. If you do not agree with me, I feel sure it is because we do not understand the same thing by the word "organisation." When you speak of organisation to most people they immediately seize upon some small feature which may be to them of more immediate interest. It may be the general arrangement of their accounts, their system of store-keeping, of dealing with their work men, of the sales department, or fifty other minor details. If you take this narrow view of organisation you will, of course, at once say that a scientific man has very little to do with it, and indeed the manufacturer as a rule, thinking of his works organisation, scouts the idea that a man of science can either know or have anything to say about it which is of any value.

Let me therefore take the dictionary definition. To organise is to "arrange or constitute interdependent parts, each having a special function, act, office, or relation with respect to the whole." If we accept this definition, which as a matter of fact we must, there is no question as to the all-important nature of organisation, for you will notice there are two outstanding things The first, "interdependent parts"; and the second, their "relation to the whole." Thus the subject of organisation really includes the whole of industry. It includes science and its relation to manufacture.

* Extract from the address to the Engineering Section of the British Association at Manchester by H. S. Hele-Shaw D.Sc., LL.D., F.R.S., M.Inst.C.E., President of the Section

It includes the relations between the employer and employee. It includes the workman and his attitude towards new devices, labour-saving appliances, and output. It includes the whole question of the supply of raw materials, and even the sale and delivery of the finished article. Taking these different features, is there any doubt that the man of science in this country can hold his own, and more than hold his own, with that of any other? The history of invention is quite enough to give a final answer to this question. Again, the British employer and man of affairs has always shown himself individually in the forefront of enterprise; as for the workman himself, he is admitted, in the matter of intelligence, physical endurance, and skill, to have no superior; while with regard to materials for manufacture, and the power of delivering goods, it need scarcely be said that the British Empire, if we take it as a whole, is the richest country in the world in raw materials, and its means of delivery of its goods is expressed by the enormous preponderance of its mercantile marine.

When we come, however, to these interdependent parts and their relation to the whole, it is there that we find the weak joint in the armour. It is in this respect that Germany can teach us a striking lesson in the *arrangement* of these interdependent parts with respect to the whole. From the top to the bottom the whole forces of their industries are so thoroughly organised that they get all that is humanly possible out of the various factors. I do not limit this merely to the wonderful organisation of any works, like Krupps, or the Deutsche Maschinenfabrik, or hundreds of other works, but I include the organisation of all the Government departments, together with the banks, the railways, and the shipping, so that every facility is afforded for the world commerce of the German Empire.

Taking only one of these details, I remember, when at Liverpool, and the battle of the Manchester Ship Canal was being fought, what facts came out as to the difficulties in the transhipment and handling of goods. The late Mr. Alfred Holt, for instance, was one of the most earnest in pointing out that the want of co-operation and organisation in getting goods from our manufacturing centres was adding largely to their cost, and actually exceeded the cost of transporting these goods across the ocean. In Germany, on the other hand, the Government steps in, and by means of special differential rates gives the manufacturer every facility, and the lowest possible rates for obtaining raw material and delivering the finished goods to all parts of the world. It was this organisation that not only rendered Germany so formidable a rival in times of peace, but makes her so powerful in war.

This co-ordination in Germany is carried out in every industry in a way we generally have little idea of. For instance, the other day, at a deputation to the Government, Mr. Runciman remarked that the difficulty of connecting the manufacturers with the commercial staffs in this country is deep-seated, but perhaps not altogether incurable. Further, that the manufacturer must realise what he can get from the universities, and the university must know what the works require. Dr. Foster, the treasurer of the Chemical Society, also said that "the Germans were so imbued with the need of pursuing modern and efficient methods of education, in applying science to industry, that they hold in contempt a country which notoriously neglects such processes"; and he attributed this contempt as partly contributory to their cheerfulness in entering into the war with us.

Now, while these remarks are undoubtedly true, they are only a part of the truth. The evil is far wider than in any special application, for, as the German knows perfectly well, there are innumerable individual cases of organisation in this country of equal efficiency to any in his country, and he is glad enough to learn from special cases. Let us take one, and I do so because it shows that the man of science is capable of industrial and manufacturing organisation, if he turns his mind to it. I refer to the case of the firm known as Barr and Stroud, Ltd. As you know, the founders of this firm were originally colleagues in the Yorkshire College (the former, Professor Barr, occupied the Presidential chair of this section three years ago), and they together invented a range-finder. Now, whatever the merit of this range-finder, it is safe to say, like every other important invention—for instance, the Parsons turbine—that the invention alone would have stood a small chance of coming into practice. In fact, to make the invention is, as a rule, the beginning of the difficulty. Professors Barr and Stroud, however, set to work to carry their invention into practice, and did so with such effect that their works, which began on quite a small scale, rapidly grew, and the first part of the new works was opened with about ninety hands all told in 1904. In the course of ten years it has increased to such an extent that there are now 1,700 employees. Those of us who have visited the works at Glasgow know the almost perfect way in which the whole arrangements are made, not merely for the scientific side, but for the comforts of the men, including the working dress, which in itself becomes a uniform. It gives some idea of the scientific side to know that it includes at the present moment twenty-three men with high university qualifications, most of them with university degrees, and many of them men who were absolutely the first on the college list in the final examinations. This industry is another illustration of the lead given to Germany by this country, because the Barr and Stroud range-finders were brought out before any of the German range-finders of the kind now being made, the Germans having followed in their lines, and copied them in many respects. I have enlarged upon this, because I cannot help pointing out that the Barr and Stroud range-finders have had no small effect in the

marvellous precision of our naval guns, and it will no doubt pass through your minds what we owe to private enterprise which started the manufactures of the turbines, range-finders, guns, and other naval features, when we think of such battles as those off Heligoland or the Falkland Islands.

Now I do not believe the Germans despise us for our want *per se* of the application of science to industry. I do not think they have much reason to; but what they do despise us for is the want of co-ordination, which I venture to say amounts to positive slackness, which they are keen enough to observe permeating the whole of this country. They see different sections, instead of being united for a common end, quarrelling with each other, filled with mutual suspicion and distrust, with apparently no common bond of union, and whereas the German is proud of the Fatherland, he sees in this country large numbers who seem, either through self-consciousness or ignorance, to be ashamed to mention the subject of the British Empire, or, what is worse, to acknowledge that any love of their country is, or could be, a mainspring and incentive to strenuous effort.

The other day Field-Marshal von Moltke stated, and there is no reason to disbelieve him, that great as was the storage of ammunition and shells before the war, the enormous demand far exceeded all expectation, and Germany found herself for a time in the same plight as her enemies; but he further stated that Germany's emergence "from this dangerous position was largely due to the extraordinary organisation, which included not merely the adaptation of their factories for munition purposes, but *capacity for work of the people*, and the *patriotic spirit of the German workmen*."

This brings me to consider what is probably the most serious feature in our national life to-day, which I have already alluded to under the heading of Education, viz., the relation of employer and workman. It is hopeless, as long as such ideas prevail as seem to do at present, to think of any sound organisation of our industrial system taking place, because the interdependent parts are not arranged (and can never be arranged until we change radically) with respect to the whole. Now, as one who has served an apprenticeship, who has taken his money weekly from a tin box with hundreds of other men, who has been a member of the Amalgamated Society of Engineers (in fact, was working as an engine-fitter when a Whitworth scholarship made a college career possible), I am the last man to put this evil down entirely to the working man. I know individually he is just as capable of patriotism as any other class. Get him by himself, even the men whose strikes have caused such despondency in the minds of our Allies, and who have seriously jeopardised the very existence of the country, and you will find (except in the sort of case to be found in all classes of society), that he, as an individual, is willing to make sacrifices, and if necessary to give himself for his country. The truth is that the canker which is eating the heart out of our industrial life is due to an entirely wrong attitude of mind. For instance, however much we may sympathise with men who see a loss of employment in the introduction of labour-saving machines, some means should be found by which they can share the benefits to the State and to their employers by the introduction of such machines. I should like, if I had time, to say something about the marvellous organisation of the Ford motor-car works in America, and how it has given the men a share in the returns of a great industry, and thereby induced them to work in a way that has enriched themselves, their employers, and their country. We have many splendid examples of this co-operation in this country. For instance, Messrs. Allen, of Bedford. Again, the employment of women in the engineering industries has taken place in many directions owing to the war. The works with which I am associated could not have undertaken much munition work without it. Some steps should be devised by which this avenue of industry is not closed to women after the war, while justice is secured for the men alongside of whom they are working, and from whom they are in many instances learning mechanical skill. Again, the questions of piecework and overtime must be seriously considered by the State, and not allowed to become the subject of disastrous disputes. Once more there is the question of a standard wage. It is against the eternal laws of nature to try to keep living beings at one dead level of equality and merit—*i.e.*, it is against the law of the survival of the fittest. The trade unions have a great opportunity of placing their country and themselves in a leading position amongst nations if they will courageously grapple with a great problem by recognising degrees of merit and corresponding degrees of payment. These are a few of the many matters which must be dealt with in the immediate future.

The matter of labour disputes is so serious as to demand plain speaking. It must be admitted that there are many employers and companies which, to satisfy themselves and their shareholders, extort the largest possible dividends and pay the smallest possible rate of wages, and do so apparently without the slightest idea that the men and boys under them are capable of education and personal influence. Can it be wondered, then, that men under these conditions are willing enough to listen to the orator who merely appeals to their fighting instincts and join in the game of grab as against the employer? On the other hand, strikes have occurred when employers have honourably carried out their obligations and undertakings, and the men have shamefully departed from an agreement made by their chosen leaders, throwing over the leaders the moment they have fancied it to their own selfish interests to do so, and without a single thought of their duty to the community as a whole.

We have recently seen the Prime Minister and other leading statesmen struggling, sometimes in vain, to bring large bodies of men to a reasonable state of mind. Is not this (and I speak without

the slightest reference to party questions) a case of Nemesis overtaking us for having in so many cases pandered to the selfish instincts of large bodies of men in order to secure their votes, instead of sternly telling them unpalatable truths?

There was recently an intensely interesting article by the late Professor Friedrich Paulson, previously Professor of Philosophy in Berlin University, published in the *Educational Review* of New York. In this article, the subject of which was "Old and New-fashioned Notions about Education," he pointed out that the whole of our educational system was going wrong, and that we could not escape the conviction that a tendency towards weakness and effeminacy was its chief trait. His three mottoes were: Learn to obey; learn to apply yourself; learn to repress and overcome desires; and he remarked with great truth under the first heading: "He who has not learned to do this in childhood will have great difficulty in learning it in later life; he will rarely get beyond the deplorable and unhappy state that vacillates between outward submission and uproarious rebellion."

Is not one of the first things the reform of our educational system?

The other day a writer in the *Spectator* said with great truth that "what Great Britain is suffering from acutely and dangerously at the present time is the absence of discipline," and a neutral writer in the *Times* remarked as follows: "The uniformity of German effort, due doubtless to their myriad well-organised, machine-like minds, though it renders them excessively tiresome people to dwell among in peace time, enables their Government to extract every ounce of energy in the conduct of a war." He further went on to say that the British Empire "could not have been created by minds like these, but it should not be forgotten that in the concentration necessary to national effort in a struggle like this the German system of self-subservience to the State has enormous advantages."

One of the tasks to which the British Association might bend its energies with the greatest benefit to the country is to bring about a reform of our educational system, so that while we do not kill individual enterprise and freedom of thought, which have contributed so largely to the political organisation and constitution of the British Empire, of the value of which we have had such wonderful evidence from our colonies and dependencies during this war, we seek to implant in the minds of young and old those ideas of discipline and service to the State, the want of which so seriously threatens the successful organisation of our industrial life.

RUSSIA'S POWER RESOURCES.

The *Engineering Magazine* draws attention to an article in the *Revue générale des Sciences* which discusses the extensive waterfalls and peat deposits that await exploitation in Russia.

Without considering the Caucasus, the Trans-Caspian region, or eastern Siberia, there are still in Russia proper great sources of hydraulic energy. In the northwest are the falls and rapids of various rivers—for example, the Volkhov with 30,000 to 50,000 horse-power, the Msta with 30,000, the Narova with 40,000 to 70,000, the eastern Duna 120,000, and the Niemen. In the north, again, the Olonetz region offers a number of available power sites, as do the rivers which flow into the Arctic. In the Ural Mountains energy could be obtained from lakes and from the rivers Chausovaya and Bielaia, and on the Valdai plateau are sites for power development. In the south and southwest are the falls of the Dnieper, 120,000 to 200,000 horse-power, and the rapids of Dniester and the central Bug.

Most of the sources of power, except in the case of the extreme northern streams, are found in regions thickly settled and already possessing considerable industrial development. Other sources, like the Duna Falls, are on important waterways, and in the case of the falls in the Olonetz region the rivers communicate with centres of power consumption.

Most of these power sites could be easily developed, and current could be supplied over long distances at a low rate. Hydraulic-power development would be intimately connected with the improvement of the rivers for navigation and with irrigation.

At present little of this potential power is utilised, except, of course, in Finland. Of the large possibilities, only the Narva Falls are exploited, and these in poor fashion. The capacity of the other twenty or thirty plants rarely runs over a few hundred horse-power, and the bulk of the Russian plants are small affairs of a few horse-power, supplying little factories, sawmills, etc.; there are also many primitive installations for village mills and similar purposes. A census of existing plants, finished by the Imperial Russian Technical Society in 1913, showed a total developed horse-power in the Empire of 250,000, of which the small plants furnished 80 per cent.

Development is, however, increasing, and better plants are being erected. Thus the importation of turbines climbs steadily, and the annual output of Russian turbines increased from 2,000 horse-power in 1900 to 7,000 in recent years. Large central stations remain extremely rare, but the series of Government undertakings, the requests for concessions and the large Stuart project in the Caucasus are encouraging signs. Legislation obstructing the erection of transmission lines needs to be altered, and especially there must be overcome great national ignorance as to the possibilities in electrical-power development, and the lack of knowledge even among technical Russians of the engineering and economic conditions governing hydro-electric installations.

Apart from hydraulic-power possibilities, Russia possesses a tremendous resource in the vast peat deposits underlying her many swamps. These

deposits constitute 7 per cent. of the total surface of the country, and are almost three times as great as the combined peat areas of Germany, Ireland, Sweden, and Finland. From the point of view of agriculture, peat deposits are classed as bad land. They tend to grow and encroach on farm lands, and for this reason, and to protect the public health, they have to be fought continuously.

From the fuel standpoint, however, these peat bogs are favourably situated, being, in general, distant from the oil and coal fields and relatively near the industrial centres. Many plants near bogs have used peat fuel for a long time. As the price of other fuels mounts, more and more peat is used; its extraction has taken on the dimensions of a large industry in many places, and involves the use of machinery. Especially in the Moscow-Vladimir district, where oil and coal are high, a good deal of investigating has been done, looking to the lowering of the cost of peat production and the use of distant deposits. The price of peat near power-plants is high, and the Government peat lands, when favourably situated, sell for good figures. The difficulty and cost of transportation are a stumbling-block in the way of extensive development.

The remedy for conditions is the construction, at large deposits, of central generating stations with long-distance transmission. The electric energy thus generated could be used also to cheapen the cost of extraction, electrical machinery for the purpose being more convenient and cheaper than steam.

The company which furnishes power to Moscow has undertaken a large project, involving the development of a peat deposit near the city of Bogorodsk. This plant will be built from the experience gained at a German plant in Friesland near Autrich, where a peat bog is being reclaimed; the peat incidentally excavated is used for power for the excavating machinery and for driving electric ploughs; the bog is to be consumed as fuel little by little; the conclusion will be the transformation of a waste area into tillable land. Another method of utilising peat when it is rich in nitrogen is to generate gas for internal-combustion engines, and make tar products, from which the fertiliser, bi-sulphate of ammonia, is extracted.

The potential importance of the Russian peat deposits for fuel can be expressed in figures. A ton of peat dried in the air to 22 or 25 per cent. moisture content has a calorific value equal to half a ton of Donetz coal, or 675 lb. of oil. Extraction, preparation, and air drying costs about $1.80 per dry ton, but this cost can be lowered by using the electric energy generated. The exploitation of the vast deposits tributary to the centre of Russia would lower the cost of fuel by a half, and the same in the northwest. The deposits belonging to the Government have been examined, and are found to run about 260,000 cubic feet per acre, equivalent to 2,300 tons air-dried. The area covered by peat deposits in Russia is about 177,000 square miles. If the same ratio holds over the country as for the Government lands, the total reserve is about 100,000 million tons of peat. This compares with coal reserves of about 80,000 million tons. The peat is constantly growing, and taking its heating value at half that of coal, it is evident that the peat reserves are about equal to those of coal. Around Petrograd half of the country is covered with peat bogs.

The exploitation of peat as a fuel requires a high degree of special knowledge. The many attempts in this direction in Russia have shown results deplorable from the technical point of view, although satisfactory financially. Continued experience will surely develop the most suitable methods, although adjustment to existing conditions may entail some expense. After the conclusion of the war, great progress in this work may be expected.

The possibility of long-distance electric transmission, as it has been developed in modern times, and the success of the scientific utilisation of peat, should open the way to the exploitation on an immense scale of the enormous deposits of peat which Russia possesses, and, along with this, the reclamation of worthless districts into agricultural lands.

AUTUMN AND WINTER FODDER.*

In view of the short crops of hay obtained in some parts of the country farmers may well be anxious to increase their stock of winter fodder. Considerable areas of aftermath will be saved for cutting, reducing the area available for late grazing, and it may be useful to consider especially in the event of a dry autumn, how a shortage of grass can be made good.

Maiden Seeds.

Sometimes a fair amount of autumn keep is furnished by "maiden seeds," but great care is necessary in the grazing of this crop if its future is not to be endangered. After the covering crop has been harvested the "seeds" should be rolled as soon as the implement is likely to make any impression on the ground. This will effect consolidation and promote tillering. Further, before being depastured the plants should be allowed to establish a firm and fairly deep root-hold as a precaution against winter frost, spring drought, and the risk of being up-rooted by stock. At the same time, if a short-lived plant, such as red clover, be allowed to reach or even approach maturity in its first autumn, the chances are that, by spring, much of it will have died. Grazing will check this and encourage branching of such grasses as may have been included in the "seeds" mixture.

Straw.

It is generally possible in winter feeding to replace hay either wholly or partially by straw.

* Special leaflet issued by the Board of Agriculture and Fisheries.

For this purpose the straws in common use are those of oats, barley and wheat. One of the chief functions of straw in a ration is to provide the bulk of fodder necessary to the health of a ruminant animal. The nutritive value of straw is usually low, but much depends on the degree of ripeness of the crop when harvested. The riper the straw becomes the greater is the transference to the seed of the most valuable nutritive matters, and the tougher it is to chew. In general, spring-sown cereals are less fibrous than winter-sown, and consequently more nutritious. Oat-straw is generally considered the most suitable for feeding, but barley straw, particularly if it contains a proportion of grass and clover plants, also forms useful fodder. Cereal straw is relatively rich in carbohydrates and uniformly poor in albuminoids, and consequently in feeding straw to stock the farmer has to arrange to increase the proportion of albuminoids in the ration. This can best be done by the addition of cakes or meals rich in albuminoids.

For feeding cattle, straw is chaffed and mixed with sliced or pulped roots, crushed cake or meal, and treacle water, and allowed to stand overnight. A slight fermentation sets up which softens the straw and further adds to the palatability of the mixture.

In order to save straw for fodder the extended use of bracken and peat-moss as litter is desirable.

Potato Tops.

The crops commonly used for supplementing bare pastures are vetches, maize, cabbages, early turnips and mangold leaves, but where a sufficiency of these is not available, potato tops may be found useful.

The tops should be cut soon after they begin, normally, to turn yellow, and be fed on grass land, but, as a precaution against the transmission of disease to future crops, should not be fed on grass which is to be broken up for potatoes in the following year. Green tops should be used very sparingly, preferably after being dried in the sun and wind. Tops bearing many blossoms or unripe fruits should be avoided, as they are likely to be unwholesome.

The tops should be collected as free from earth as possible, and be fed in small quantities along with other food.

White Mustard.

White mustard grows very rapidly and may be broadcasted upon stubbles broken up by the cultivator or disc harrow. Sown as late as the end of August, mustard will usually yield good food by the end of November. If not required for sheep feeding the crop may, with advantage, be ploughed in as green manure. From 14 lb. to 16 lb. of seed, together with 1½ cwt. of superphosphate per acre, should be sown.

Reeds.

Another plant not to be despised in times of shortage is the reed.

The common reed (*Arundo phragmites*), which grows luxuriantly in wet or marshy places, is mainly used, if at all, for thatch and bedding. The straw is too coarse and brittle to make really good litter, but is admirably adapted for thatch, and where available may well be used for this purpose instead of ordinary straw. For feeding purposes young reeds are suitable. The tops of the shoots are tender and succulent and are readily eaten by stock. As the plant matures, however, it becomes almost incapable of digestion, and unless specially treated would be quite unfit for food. During June and July the more tender portions of the plant may be dried and chaffed, and fed instead of straw. Later the greener portions may be converted into silage and thereby softened and rendered more palatable.

Care, however, should be taken to feed only small quantities along with roots and concentrated feeding stuffs.

Gorse or Furze.

Gorse or furze, which grows naturally on waste places, was used formerly in this country as food for stock, and was even specially cultivated for that purpose. Two types are commonly met with —the ordinary prickly gorse, and "French" or foxtail gorse, which is relatively free from spines. The latter requires less preparation for stock feeding and is, therefore, generally to be preferred, but ordinary gorse, once it has been thoroughly pulverised, may also be fed to stock with good results.

Gorse possesses the great advantage that it can be grown on poor thin soils where other plants would fail, and it will greatly improve such soils by its growth. Naturally, however, it thrives best on good well-drained soils: it will not do well on cold clays, or damp peaty soils, or on chalk.

Where foxtail gorse is specially grown for fodder the seed is drilled in rows 12 to 24 inches apart in April or May, on clean ground, at the rate of 12 lb. to 15 lb. per acre. Gorse seedlings are slow in growth, and it is most important, therefore, that weeds should be kept in check. The first cutting is usually made in the second winter after sowing, from November to the end of February. Thereafter the crop may be cut annually or biennially as found expedient.

In an experiment conducted on light sandy land at Woburn, "French" gorse yielded 11 tons per acre in its second winter.

Before being fed to stock, gorse is generally crushed between rollers, or otherwise pulverised. It should not be allowed to lie for long in bulk as it ferments and quickly becomes sour and unpalatable. In the case of old-established gorse only the green tops are fit for feeding. Old gorse covers, however, may be reclaimed by cutting down the woody plant as close to the ground as possible, and freely dividing the roots. Subsequent young growth will be available for cutting at one or two years' growth as may be required.

Gorse is a highly nutritious fodder, and has

proved satisfactory with all classes of farm live stock, more particularly with horses and milch cows. It should form, however, only part of the ration, as when fed in excess it proves too heating. This effect may be counteracted by giving occasionally a bran mash or a daily allowance of roots. Horses and cows may receive up to 20lb. per head daily. In the Woburn experiment already referred to, the gorse was put through a gorse-cutter and fed to sheep on swedes. In the fresh state the sheep ate, readily, up to 2½ lb. per head daily, and throve well upon it.

DRY-FARMING IN INDIA.

Experiments in dry-farming have been continued in India during the year 1913 14, and some account of them is to be found in the Report on the Progress of Agriculture in India for that period. Work was conducted by Mr. Howard at Quetta, where the conditions of water in the sub-soil resemble those in the best dry-farming areas in Western America, and where the rainfall is more or less consistently insignificant. By suitable methods of moisture conservation, it has been found possible to effect a great saving of irrigation water in Baluchistan. In the case of the wheat crop good results were obtained by giving only one watering before sowing (intead of the usual six to eight), and afterwards conserving the soil moisture by means of a surface mulch produced by lever harrows

The experiments in other places of moderate but uncertain rainfall relate to the evolution of standard farm practices which must vary according to local conditions Thus, in Mysore deep ploughing and use of the sub-surface packer for consolidating the land have been found to increase the yield of *ragi* (*Eleusine coracana*) in a season of scanty rainfall, while in the United Provinces hot-weather ploughing for wheat effects a saving of water when there is a great demand for it. The Departments of India already understand the general principles underlying dry-farming, and the matter is now largely one of development of improved practices by local demonstration.

In Bombay experiments have shown that in a year of moderate rainfall typical dry-farming methods are of distinct advantage in conserving moisture, but that in heavy black soil even the most careful cultivation will avail nothing in a "famine" year. Before studying further the question of dry-farming, it is considered necessary to classify the soils of the East Deccan where the rainfall is very light and to ascertain their physical properties, which make the problem in India different from that in the dry-farming regions of the United States.

In this connection the report quotes some observations of Mr. Keatinge, in which he speaks of the different conditions in the two places. "Another point," he says, "in which the dry-farming regions of the United States of America have an advantage over us is that the rainfall is far more consistent and better distributed. They know fairly well what rain they can count on, and do not get such excessive downpours in a day as we often get With us a tract which usually gets less than fifteen inches of rain in the year may suddenly get twenty inches in two months; or, contrariwise, in a famine year a tract may get less than two inches in a year. Further, the heat of the sun, and consequently evaporation, are far less in the United States of America during the greater part of the year; and in the late summer, when the heat there is considerable, the crops cover the ground. Last but not least must be mentioned the fact that they have at their disposal far better teams and far better implements than our farmers have."

SPANISH ORANGE TRADE AND INDUSTRY.

Official statistics, published in 1914, placed the value of the 1913 Spanish orange crop at 68,930,220 pesetas (£2,757,200), four-fifths of which represented the production of the Valencia district. But, figuring on a basis of 6,000,000 cases, the number exported from the Valencia region during that season, and an average value of 10 pesetas (8s.) a case, packed ready for shipment, this estimate appears to understate the real value for all of Spain by a considerable amount. Nevertheless, accepting it as true, the value given for this district, nearly £2,000,000, was considerably more than that of all the other crops of the district combined. As a yearly influx, this income is of supreme economic importance, being distributed among many large and small orchard owners, and thousands of male and female labourers, who derive a living from the orange industry seven months of the year. Judged by the cost and standard of living it is so large an amount that it cannot suffer heavy diminution without affecting the welfare and purchasing power of the district as a whole.

The steady increase in the production of oranges for several years is due to new plantings and to the progressive elimination of insect pests by the hydrocyanic-fumigation process. Markets also have been developed, but as they have not kept pace with the production, each year sees a larger prospective surplus, the possible ill-effects of which have not escaped the attention of the orange interests But fortunately, or unfortunately, according to the view-point, the apparent over-supply of each recent year has disappeared as a result of natural causes. The 1912 crop was destroyed by hailstorms before maturity to the extent of more than half a million cases, yet an ample supply of oranges remained to meet a strong demand in English and other European markets, and to produce the highest export figures ever known. The 1913 crop was one-third marketed in January, 1914, when the remainder was severely frost-bitten, leaving an actual shortage, which reacted so favourably on market conditions during

the balance of the season that the total value of the crop was higher than that of the preceding season.

The 1914 orange yield is said to have been the largest of all. An unofficial estimate, made just before its maturity, placed it at 8,000,000 cases (165 lbs. each) for export. Since orange statistics are not kept by official or commercial bodies, except by the volume of exports, this estimate cannot be verified, but it is thought to be conservative.

With the war as the only disturbing factor before the season opened, it was predicted that there would be a surplus of from 3,000,000 to 3,500,000 cases, but in the face of this man-made catastrophe the possibility of loss from sudden meteorological changes was overlooked. Therefore the district was little prepared for the heavy frost in February, which damaged about 1,500,000 cases, followed ten days later by cyclonic winds that further depleted the crop. The total loss is not known, but may reach 2,000,000 or more cases. Up to March 30th, 1915, nearly 3,500,000 cases had been exported by sea, and during the remaining weeks of the season the shipments were expected to reach 1,500,000 cases. Indications at the end of March were that the season's overland trade to France would reach 600,000 or 700,000 cases; hence there will be little, if any, of the anticipated surplus.

It appears from a report by the United States Consul at Valencia, that when the war broke out the orange interests of the district were greatly perturbed, and in numerous mass meetings held in all important centres the Government was urged to use its influence to find new markets in America, to regulate ocean freight rates by subsidising a steamship line between Bilbao and England, to normalise exchange facilities, and to compel improved railway service and cheaper rates in order to increase the domestic consumption of oranges.

A delegation of orange men went to the United States to investigate that market and to see if it was possible to inaugurate direct trade with that country, but it was soon discovered that competition with California and Florida fruit was not feasible. The Government met the demand for the tri-weekly steamship service from Bilbao to Falmouth, but the line was unsuccessful as a trade developer, and notice of discontinuance soon followed. The banks were unable to extend credit facilities on account of the moratoria in the United Kingdom and France; and bills of exchange were accepted, subject to payment of principal, only on receipt of telegraphic or mail advice of liquidation by the payer.

The movement to create a wider demand in Spain for Valencia oranges attracted more attention locally than any other proposal growing out of war conditions, but it produced no better result. Up to that time no interest had been shown in the domestic market, possibly because favourable conditions in foreign outlets served to distract attention therefrom; but more likely it was on account of the expensive and slow transportation service to urban centres, where the trade had to be developed. It was common knowledge, for example, that oranges could be shipped in less time and at cheaper rates by water from Valencia to Bilbao *viâ* England than by rail direct. Efforts were therefore made to secure important reductions in railway rates, and fast goods services to the leading Spanish cities. Unfortunately, the railways could not meet the demands in full, and the slight concessions granted were insufficient to encourage the movement. The reduced rates were based on mileage, the minimum being about 21s. per metric ton (2,204·6 lb.) for 500 kilometres (312·5 miles) or less; and the maximum 37s. per ton for 1,000 kilometres (621 miles) and above.

The 1914 orange season opened in October as usual, and at the end of the year the shipments to the United Kingdom, the Netherlands, and Scandinavian countries were above the average. From a monetary standpoint this preholiday period was highly successful for the shippers participating therein, but their number was small; the packers, as a class, could not take their customary places in the trade because the usual supply of English and German money was not forthcoming, and having no capital of their own they were without means to buy fruit and packing materials. Growers, therefore, had the choice of leaving oranges to spoil on the trees or of packing and shipping on their own account. Many at first preferred to do the former, but when the success of the first consignments became known pessimism gave way to speculation, and it was not long before the wharves of Valencia and other ports were crowded as never before with fruit awaiting exportation. Fortunately, much of it was held over because just at the time there was an acute scarcity of shipping.

Operations at the end of 1914 showed that the important German, Austrian, and Belgian markets were eliminated for the season, and overland shipments to France were about one-half normal. These losses were partially compensated by heavier shipments to the United Kingdom and the countries of northern Europe, and by new trade with Italy and America, leaving a net decrease of only 83,000 cases compared with the 1913 figures.

RESOURCES OF THE KAIHSIEN DISTRICT OF CHINA.

Kaihsien is a city of about 40,000 inhabitants, just north of Wanhsien, in the extreme eastern part of Szechwan Province. It is situated on a small but navigable tributary of the Yangtze River. The district under review is somewhat larger than the political division called the "Kaihsien district," and is bounded on the north by Chengkow, on the south by Wanhsien, on the west by Suiting, and on the east by Kweichowfu. This region contains

a population of 600,000 to 800,000, but the district is very sparsely settled.

The principal crops grown in the Kaihsien district are peas, beans, rice, maize, Irish and sweet potatoes, tobacco, cotton, millet, and sugar-cane. The chief winter crops are wheat, peas, beans, and Irish potatoes, while rice, maize, millet, sweet potatoes, sugar-cane, and tobacco are harvested in the late summer. A considerable quantity of wood oil is also produced. The hills in the northern section of the Kaihsien district have forests of oak, pine, and cypress.

A considerable amount of salt is produced in the Kaihsien district. The principal centre of this industry is Wen-tang-ching, eighteen miles north of Kaihsien, on the same river. The brine is found very close to the surface, and is mostly collected on the banks of the river during the season of low water. The coal found in this region is both cheap and abundant, and is used in evaporating the brine. It is brought down by river from Ma-chia-Kou, a small town four miles to the north of Wen tang-ching. The coal is not actually mined at this place, but is brought overland by coolies, a distance of nine miles, at a cost of about 2s. 11d. per ton. Iron ore is found in the Kaihsien district, as in most other parts of Szechwan Province. It is smelted in coal furnaces and is exported as pig iron to down-river points. Lime also is found, and limekilns are scattered throughout the hilly country in the northern section of the district. The rice fields are sometimes sprinkled with slaked lime to improve the quality of the soil.

Although the agricultural methods in use throughout the Kaihsien district are crude, there is not much prospect of selling agricultural machinery. The farms are small and the people comparatively poor. Considerable cloth weaving is carried on in the country districts, but it is done in a small way at a great many different centres. From a report by the United States Consul at Chungking it appears that there is not much chance of introducing textile machinery at the present time: but if factories are started and the industry develops to any extent there ought to be a market for cheap looms of simple construction. Mining machinery might even now be sold to advantage, both for coal and iron, and a modern smelter might be established very profitably at Ma-cha-kou or Wen-tang-ching. With the cheap labour above mentioned, and the extensive deposits of iron and coal, there is no reason why the Kaihsien district should not become, in the course of time, an important manufacturing and industrial centre.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Coloured Cotton Fibre.—The prominence that has been obtained for reports of reputedly successful efforts to grow cotton in various colours is hardly of the most auspicious kind. Cotton has been grown in a limited number of more or less pronounced colours for, doubtless, thousands of years, and it is observable that such varieties have almost uniformly been considered less valuable than similar fibre in a good white. There can be no wish on any hand to disparage attempts to improve the coloration of raw cotton or to belittle systematic study of its culture. It trenches, however, upon the absurd to talk of presently substituting cultivated colours for dyed colours, and speculations based upon that prospect may be dismissed. There is no considerable difficulty in finding materials to dye cotton to as good shades as have hitherto been produced in the course of nature, and probably there will be no more in matching the tan, green, olive-green, and bronze colourings reported to have been grown lately in the United States. The opinion has been confidently expressed that the culture of a black cotton is not impossible, and the foundations of that belief need not be questioned. Whether there is actually much demand for the article is another affair. Black is presumably just black in the popular mind, but dyers who use and recognise some eight or ten separate shades of black are apt to find the description a little crude. In no case are the textile industries likely to run out of materials for black dyeing, for the sulphur blacks are fairly accessible and cheap, and as long as there is a supply of aniline oil a fast black can readily be developed upon the fibre. Upon the analogy of cottons at large the shade of naturally coloured fibre might be expected to vary between plant and plant if not between part and part of the same fibre and to vary also according to ripeness, to seasonal influences, and to the length of time in storage. Leaving all such considerations aside, there are practical difficulties in the way which far more than offset the superficial advantage of avoiding the dyeing process. White or whitish cotton can be mixed together in the loose, be worked in bulk and dyed to such shades as may be determined upon later. Necessarily, separately coloured loose cottons must be kept apart. The machines must be free of one colour before another can be put in, and adjoining machines cannot work upon differently coloured material for fear of contamination. Such inconveniences are not the only ones, but it is as well that their reality should be recognised. Perhaps the most that planters can do in practice is to provide a drab-coloured mass of fibre less handy for general purposes than the white that they might produce with less trouble. There is, of course, nothing new in utilising natural in place of dyed colours. The original khaki was the muddy colour of the brown cottons from which the fabric was made. In silk the brown of the tussor worm is sufficiently well known, and most knitted underwear is described as "natural." Not enough black and brown wool is grown to satisfy the demand for the nominally natural mixture shades, and the result is that art steps in to the aid of Nature. Nature in a general way cannot

better assist textile art than in furnishing materials that are easily reduced to a fair white, and that can be dyed to the shade which may be in vogue. The dyer's troubles are oftenest only aggravated by the existence of colour upon the material which he has to treat.

Osage Orange Wood.—A certain recklessness is observable in reports of the discovery of a new dyewood, osage orange, grown in Texas and Oklahama, and stated to furnish a yellow much in demand for textile work. Novelty can certainly not be claimed at this date for a dyestuff that is useful enough in its own way, albeit presenting a dye of less concentration than a better known wood of which there is no scarcity. Dyers in this country prefer fustic to osage orange, for the principal reason that they can obtain it more cheaply and certainly. Were fustic to fail them there are various vegetable sources within these islands yielding practically the same colour-principle; but apparently there is enough on hand to meet all possible requirements, with virtually unlimited quantities ready to be cut and shipped.

Budget Changes.—The new Budget proves to be of less specific moment to textile industry than at one time seemed probable, and with the removal of motor tyres from the list of articles liable to import duty the industry almost ceases to be directly concerned in the fiscal changes. Tyres are composed of strong cotton fabric as well as of rubber, and the manufacture of tyre cloths has risen to the dimensions of a quite considerable trade. The £15 millions or so of imported silks make a conspicuous mark for those searching for taxable imports, and it is not clear why this source was passed over. The odds and ends of cotton lace, trimmings, and embroidery imported into this country run normally into some £12 millions, and there are respects in which these may be coupled with silks as articles eligible to bear tax. In the matter of the increased cost of postages the textile manufacturing trade is almost disproportionately little concerned. There are doubtless manufacturing establishments with heavy bills for postage, but over a large part of the trade correspondence is remarkably light and brief. Bargains are made by word of mouth on the Exchanges—further negotiations concerning them are mainly verbal—accounts are collected frequently by hand, invoices are few and large in amount, and a visitor sees with surprise how mills both large and complex are managed with an insignificant clerical staff. The heaviest expenditure in postage is incurred by those shippers who forward myriads of patterns by post to customers oversea, and were the rise in inland rates of postage to be followed by an equivalent advance in foreign rates the addition to distributors' costs would become serious.

Machines and Hand Production.—The efforts of the Governor of Bengal to buy in India such Indian-made handkerchiefs as he had been wont to get in Edinburgh have attracted recent notice. Nobody discoverable in India knew where the articles could be bought, and inquiry had to be made in Scotland to ascertain their source. British manufacturers cannot be called anything less than well informed about the class of articles made by their own neighbours and competitors, yet such experiences as Lord Carmichael's are not unparalleled in this better-organised country. A case is known, for example, where reference had to be made to New York to learn the name of the producer of an article made in the next street to the English inquirer's address. The want of knowledge was by no means treated as a matter of course, even though it could be pleaded that the goods in point were not old ones. The incident of the handkerchief was used in Bengal to point some remarks upon the general desirability of fostering light, agreeable and artistic employments in which all the members of a household may take some part. The common fate of these domestic employments is to be devoured by factory production, and it is one of the less amiable features of modern industry that it has no scruple in breaking down idyllic occupations by the force of its machines. Native patterns are copied without remorse and put upon the market, if sales appear to warrant, at prices which leave the craftsman no chance. A process that has raged through the East, and been carried into Africa and elsewhere, has had its counterpart in this country. On the evidence of some surviving textile handicrafts in this country promoters of small industries cannot too earnestly be urged to seek directions in which it does not pay the owner of machinery to follow. Explicit advice upon the point can hardly be given, but it can be said that the presumptively largest colony of hand-loom weavers in England are people weaving bordered mats too small, in view of the number of changes involved, to be profitably woven upon power machines. The danger-point is reached by a small industry when it has built up a business of a certain size in goods of one distinct character. Probably it is beyond practical possibility so to diversify the products that their family character is lost, for in that case they are all too likely to lose their attraction for wearers. What is certain is that factory competition cannot be trusted not to break into any little sphere that skilled craftsmen may succeed in creating.

Mill Lighting.—In their recommendations the Departmental Committee upon the Lighting of Factories and Workshops confine themselves to matters affecting the illumination of floors, passages, and stairs, with a view specifically to the prevention of accidents. Their report goes a good way further and summarises measurements of the intensity of the light falling, not upon the floors, but upon the point of work in a number of

factories, textile and other. It will be found a most instructive handbook for those who have to do with illumination, natural or artificial, and one not unlikely to encourage manufacturers to think of having the lighting of their own rooms recorded. Citation of an instance or two will show what some ascertained differences in lighting have been, and it assists understanding to realise that in the regular saw-toothed, roof-lit weaving shed the normal daylight factor is some 2 per cent. of the light outdoors. In one large weaving-shed examined the mean daylight factor at the loom was 5 per cent., and in a small one was ·20 per cent. These data give the extremes, but it may be believed that smaller differences are material, and that it is better to have a mean of 3 than of 1·5 per cent. Some experiments made with seamstresses sewing coloured fabrics with self-coloured threads show that good illumination is especially requisite in treating coloured materials, and that in point of fact ten times more light may be needed for work on dark colours than on light ones. Artificial illumination is more under an occupier's control than daylight, but it is apparent that lighting is not uniformly good. In the best recorded instance the mean strength of light at the loom was 8·7 foot-candles, and in the worst case rather less than 1 foot-candle. Differences as great are recognised between several spinning rooms and carding rooms, and the tabulation of a variety of specimen cases cannot fail to stimulate interest in the subject.

NOTES ON BOOKS.

VICTORIA AND ALBERT MUSEUM.

(1) Catalogue of the Schreiber Collection of English Porcelain, Earthenware, Enamels, etc. Vol. I. -Porcelain. By Bernard Rackham. 2s. 6d.

(2) Guide to the Collection of Carpets. 1s.

(3) Catalogue of a Collection of Miniatures in Plumbago, etc., lent by Francis Wellesley, Esq., 1914-15. 6d

(4) Tapestries. Parts I. and II. 6d. each part.

The war would seem to have interfered but little with the activities of the Victoria and Albert Museum. We have before us a number of catalogues produced during the year; each of them is a well-printed and presentable volume; each is fully illustrated, and two of them, at least, must have involved a very considerable amount of research and labour on the part of their compilers.

The original catalogue of the Schreiber Collection was published in 1885. Since then a great advance has been made in the study of English pottery and kindred arts, and this has rendered necessary a considerable expansion and revision of the material. The new edition will consist of three volumes, of which the first deals with porcelain, while the second will deal with earthenware, stoneware etc., and the third with glass and enamels.

The Schreiber porcelain belongs for the most part to the eighteenth century, when the manufacture was established and reached its zenith in England. The catalogue contains interesting notes on the wares of Bow, Chelsea, Derby, Worcester, Longton Hall, Plymouth, Bristol, Liverpool, Staffordshire, Swinton, Lowestoft, Nantgarw, Coalport, and some short account of Chinese porcelain decorated in England, and of German (Meissen), Chinese, and French (Sèvres) ware. In addition to these general notes, the catalogue supplies a detailed description of each particular exhibit, while there are nearly 100 illustrations of the principal specimens.

The "Guide to the Collection of Carpets" gives a concise and informative description of the industry as carried on in Persia, Turkey, the Caucasus, Central Asia, China, Spain, North Africa, and England. Full justice is done to the work of the Royal Society of Arts in the eighteenth century in encouraging the making of carpets in this country. During the years 1757 to 1759 the sum of £150 was awarded to craftsmen engaged in carpet-making. Thomas Moore, of Moorfields, and Thomas Whitty, of Axminster, received premiums in 1757, and Whitty received further awards in the next two years. Passaver, of Exeter, and Jeffer, of Frome, also received premiums. There can be no doubt that the bestowal of these awards had a very considerable effect in encouraging the industry in its earliest stages, and it is recorded in the Society's *Transactions* (1783) that by these awards the manufacture of carpets "is now established in different parts of the kingdom, and brought to a degree of elegance and beauty which the Turkey carpets never attained."

The Guide is enriched by 47 full-page plates, which give as good an idea as can be conveyed in black and white of objects which owe their chief beauty to their delicate and harmonious colouring.

The miniatures described in the third catalogue under notice illustrate a few kinds of monochrome portraits executed chiefly in the seventeenth, eighteenth, and early nineteenth centuries. The illustrations include works by Loggan, Faithorne, George and Robert White, and Thomas Forster, who are generally considered the best exponents of the art. It is interesting to see that two of the miniatures included in the collection are the work of Johann Wolfgang von Goethe. Another specimen of note is the portrait of John Dryden by J. Richardson.

"Tapestries" contains excellent reproductions (three in each part) of well-known pieces in the Victoria and Albert Museum. Those illustrated in Part I. are "Chinoiseries," signed by John Vandrebanc, a tapestry weaver at one time established at Greek Street, Soho (late seventeenth or early eighteenth century); "Susannah and the Elders," probably Brussels work about 1500, and

"The Three Fates," also Brussels work, of the early sixteenth century. Part II. contains three collotype illustrations of "Children Playing," a set woven at Mortlake in the second half of the seventeenth century.

GENERAL NOTES.

Radium as a Fertiliser.—During the last year a series of very careful experiments has been conducted by Mr. Martin H. F. Sutton at Reading, with a view to test the value of radio-active ores as fertilisers. Mr. Sutton's interest in the matter was first aroused by statements in various scientific journals as to the somewhat surprising results which were said to have been obtained in Cornwall through the application of this ore to growing crops. The results of his first experiments led him to the conclusions, (1) that while in some cases plants dressed with radio-active ore had given better results than the control plants, the improvement was not of such a nature as to warrant the assumption that so expensive a commodity as radium could profitably be applied to crops; and (2) that very weak dressings of radio-active ore were quite as effective as strong ones, if not more so. A second series of experiments was then undertaken, in which the greatest possible care was taken to check the results. A summary of these results was recently prepared by Mr. Sutton, and the conclusion to which he was led was that in the particular experiments which he had conducted, at any rate, there was nothing to suggest that radium is likely to prove the wonderful stimulant to plant growth which some people have expected it to be.

Studio of Practical Design.—Under the auspices of the Imperial Arts League, a studio has been opened at 16, Dover Street, Piccadilly. It is intended to fill the gap which exists between the School of Art teaching and the practical work in the trade studios. Highly-skilled teachers, with complete technical knowledge of the industries, give instruction under the direction of Mr. W. G. Paulson Townsend, editor of *The Art Workers' Quarterly* and *The Annual of Art Work*. The application of design in relation to each particular branch of industries and craft is studied, and instruction is given in design for printed and woven fabrics, wallpapers, furniture, woodcarving, pottery, metalwork, embroidery, and lace. Hitherto the Germans have supplied our manufacturers with a large number of designs, which could have been produced by us had more attention been given to the technical requirements of trade. There is sufficient designing talent available in this country to improve our industrial art up to any conceivable standard of excellence, and with proper direction and due encouragement it is possible to impart new life to our art industries. The promoters of this studio aim at the improvement of British industrial design through the co-operation of the manufacturers and distributors. Periodical visits to manufacturers' workshops are arranged, so that students can obtain a more complete knowledge of the processes of production than the ordinary studio or school can provide.

Banana Flour.—Banana flour, according to the *Colonial Journal*, is now being used as a food in the French base hospitals. The banana yields about a quarter of its weight in meal, and the cost of meal in the West Indies is about 2*d*. per lb. Mixed with wheat flour it makes excellent loaves and cakes, and if wheat continues to advance in price it might be well to take a leaf out of the German book and use a second ingredient. This loaf is said to be quite as nutritious as the wheaten.

Reinforced-concrete Tramway Sleepers.—A writer in the *Commonwealth Engineer* describes the reinforced-concrete sleepers that have been laid in Adelaide to carry tram rails. The sleepers used are known as the "Joseph Timms." They are reinforced in conjunction with a metal shoe, on which the rail rests. The shoes are connected with reinforcing rods, and these are strengthened by intervening braces. The whole forms a truss bridge, which in itself is very strong, and is further strengthened by the addition of concrete. The ironwork of the sleeper is placed in a mould into which the concrete is poured, and the necessary tamping is done to ensure that every crevice is filled. The bottom of the sleeper has a concave surface, which is considered an improvement on the usual flat bottom, as it gives a better grip of the road bed. When the sleepers are laid the rails do not come in contact with the concrete, and all vibration is taken on the shoe. The initial cost per sleeper is, of course, considerably higher than in the case of wood or steel, but the durability is said to be immensely greater.

Siberian Trade Channels.—Attention is drawn in *Gas and Oil Power* to the investigations conducted during the past winter by the Siberian Association for Shipping, Trade, and Industry, which is now running its steamers to the estuaries of the Ob and Yenisei Rivers. The object of the investigations was to study the local markets and to organise extensive purchases of Siberian products, and the sale of such articles on a commission basis. The manager of the company has visited the most important producing centres of Siberia, such as Novo-Nikolayevsk, Atchinsk, Krasnoyarsk, and Omsk. The imports cover a wide range of articles, from agricultural machinery and electrical appliances to small domestic articles. The original plan of the organisation of the exchange of goods between Great Britain and Siberia has been widened, and the association has decided to extend its operations in the exchange of goods between Russia, England, and America, through Scandinavia. To utilise the natural wealth of the Siberian rivers, the company is establishing a fish cannery at the mouth of the Yenisei River.

Journal of the Royal Society of Arts.

No. 3,282. VOL. LXIII.

FRIDAY, OCTOBER 15, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

HOUR OF MEETINGS.

The hour for the Ordinary Wednesday meetings of the Society and for the Cantor Lectures will, until further notice, be 4.30 p.m., instead of 8 p.m. This change has been made to meet the convenience of Fellows owing to the darkening of the streets at night.

CANTOR LECTURES.

The Cantor Lectures on "Oils, their Production and Manufacture," by F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.T., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures, which have been published separately and are still on sale, can also be obtained on application.

EXAMINATIONS, 1915.

The changes in the system which were announced in the report on last year's examinations were satisfactorily carried out, and the duplication of the examinations—that is to say, the holding of them at two dates in the year instead of one—has on the whole proved a distinct success.

The most convenient date for holding such examinations as those of the Society has long been a matter of discussion. It is obvious that they should be held as near as possible to the end of the educational session. Now the date of this session varies in different localities, and it also varies as regards the more advanced or more elementary stages of instruction. At different times various proposals have been made, but it has never been found possible to secure unanimity.

In the course of last year certain inquiries were made by the Education Department of the London County Council with regard to the unification of the various examinations for which their schools send up candidates. Although the object of this inquiry was not attained, the practical outcome of the discussion was a proposal on the part of the Society to hold its examinations twice instead of once a year, so as to meet the requirements of those who preferred the earlier, and those who wished for a later, date. The offer was favourably considered by the Education Committee of the London County Council (the education authority for London), but the objection was raised that the Committee could not undertake to superintend two full examinations. The original proposal was therefore modified, so far as London was concerned, and it was arranged that the Elementary Examinations should be held before Easter, and the Advanced and Intermediate Examinations about Whitsuntide. As it was certain that some at all events of the centres outside London would not care for this arrangement, it was decided that in the provinces the whole of the examinations in all stages should be held twice in the year, the date for the first examination being fixed for March 22nd to 31st, and for the second examination May 10th to 19th.

The result was that in the Administrative County of London arrangements were made for the Elementary candidates to be examined in March, and those of the two higher stages in May. Throughout the rest of the country it was open to any school to hold its examinations either in March or in May, or if they preferred it at both dates. It would no doubt have been more satisfactory had it been possible to carry the change out thoroughly, and hold two examinations in all stages and in all the subjects. It was, however intended that the

arrangement for the current year should be merely tentative, and it was hoped that next year it might have been possible to organise two complete examinations, one in April and the second in May. But this anticipation has been brought to nothing by the upset which the war has caused in all educational arrangements, and all that it has been found possible to do has been to repeat the 1915 arrangements in 1916.

It should be understood that the new system involved a considerable concession on the part of the Society, inasmuch as the expenses were heavily increased, while a good deal of additional unpaid work was thrown on the Society's staff. It was, however, hoped that there would be a large increase in the number of candidates, and that their additional fees would reduce the loss, though they were not likely entirely to meet it. These calculations were entirely upset by the war, and instead of an increase there was, as set out in other parts of this report, a very considerable diminution in the number of candidates and a corresponding falling-off in the receipts, which only amounted to £3,646, as compared with £4,320 last year.

As the expenses of the examinations appear in the balance-sheet as £4,522, there is a loss of about £875 on this head. It should, however, be explained that this is not a loss on this year's working, since the receipts are those of 1915, and the amount on the other side represents the payments on the previous year's examination. The receipts, therefore, are diminished in consequence of the reduced number of this year's candidates, while the payments are those incurred for the larger number examined in 1914.

It is certain that the Society cannot stand such a drain on its resources, if it is to be continued in the future, and unless it is found that the receipts next year bear a more satisfactory relation to the outgoings, the whole question will have to be reconsidered. The Society has never made a profit on its examinations. For many years they were carried on gratuitously and at a serious annual cost. In 1880 a small fee was imposed, and since that date the examinations may be said to have been almost self-supporting. For a few years past there generally has been a trifling profit, but on the whole the Society has expended a very considerable sum of money in carrying out a work of admitted public utility, work which in any other country in the world would certainly have been undertaken by the State.

Financial considerations, however, apart, the experiment may be said to have proved a decided success. No difficulty whatever was found in carrying it out under the new system, and it appears to have met with general approval. It need hardly be doubted that under normal conditions the steady growth in the number of candidates which, as shown on the diagram on page 972 has been practically continuous for more than thirty years, would have been encouraged to even a more rapid rate by the additional facilities afforded, and there can be no reasonable doubt that in any ordinary year the number of entries would have considerably exceeded any that the Society has ever had to deal with.

It was, however, quite certain as soon as the war broke out that the examinations would be unfavourably affected in the same way as all other institutions and undertakings, and as a matter of fact far heavier losses were anticipated than were actually realised. Until the returns were received it was quite impossible to say what the actual numbers would be, though all inquiries showed that there would be a very considerable diminution on the numbers of 1914.

It is to be remembered that a large proportion of our male candidates in the two higher stages are of military age or just below it; and, further, that as a larger amount of overtime is now being worked, candidates have no time to attend evening classes. Many also of the young women who would ordinarily have been working for the Society's examinations have now taken the places of clerks and others who have enlisted. It appears certain that the falling-off in the numbers attending classes, especially those principally supported by young men, has been very great. In some of the large London Polytechnics the numbers of students for the winter session last year were as much as 40 per cent. below those of the previous year; and in the London County Council Commercial Institutes, which supply a considerable proportion of the London candidates, there was a diminution of about 30 per cent.*

* A recent report of the Board of Education, speaking of the effect of the war in diminishing the number of students at institutions supported or subsidised by Government, says: "For the Technical, Art, and Evening Schools it is not possible to give even approximate figures; but a number of the larger institutions have estimated the drop in the number of students owing to the war at points ranging up to 50 per cent., and averaging about 26 per cent." The Board a short time ago issued a circular announcing the discontinuance or the suspension of certain of its examinations.

The total number of entries for this year's examinations was 32,129—14,427 for the March examinations and 17,702 for those in May. The total shows a falling-off of 5,844 as compared with last year, when there were 37,973 entries. It should be understood that these figures represent, not the number of individual candidates, but the number of papers applied for. The falling-off amounted altogether to 15 per cent. In the County of London there was a deficiency of 28 per cent. In the provinces generally the deficiency was only 11 per cent.

There were 221 centres for the March examinations, and 252 for the May. 80 centres took both examinations. Last year there were 406 centres.

The number of candidates who actually came up for examination was 23,269. These 23,269 candidates worked 29,526 papers—Advanced 4,592, Intermediate (including Theory of Music 509) 11,350, and Elementary 13,584. Comparing the number of papers worked with those applied for we find a difference of 2,603 or 8.1 per cent. Why it is that so large a proportion should fail to present themselves after entering and paying their fees it is difficult to understand. The percentage this year is a little larger than usual.

The numbers of papers worked were divided between the two examinations as follows:—

	March.	May.	Total.
Advanced Stage . .	1,397	3,195	4,592
Intermediate Stage	4,043	7,307	11,350
Elementary Stage .	8,081	5,503	13,584
	13,521	16,005	29,526

As in 1914 there were 29,042 candidates, who worked amongst them 35,422 papers, the diminution this year is in the one case 5,773, and in the other 5,896.

The number of candidates examined in 1914—29,042—was the highest ever attained. The previous highest number of candidates entering for the examinations since 1883, when the present system began, was reached in 1911, when the total amounted to 28,644. In 1912 there was a decrease of 587, and in 1913 a further fall of 768, due to reasons stated in previous reports, and anticipated.

In addition to the 23,269 examined in the annual examinations, there were 453 candidates in Colloquial Modern Languages. The total number of candidates who were examined in all subjects by the Royal Society of Arts during the year ending July last, was, therefore, 23,722. Last year there were 29,971.

The general results of this year's examinations are given in Table A (page 967), and a comparative view of the numbers in the Higher Stages for the last six years (1910-15) is given in Table B (page 968). Tables C and D (page 969) show the percentage of successes and failures in all subjects of the two higher stages for the present year: while the percentage of successes and failures in all stages for the past six years are to be found in Table E (page 969). Table F (page 969) gives the number of candidates, papers, and subjects in the Elementary Stage since 1905. Table G (page 969) shows the number of papers worked in all stages during the last eleven years. Tables H and I (page 970) show the percentage of failures in the different subjects of the two higher stages for the last six years. Table K (page 971) gives the numbers of candidates examined during the same period. In Table L (page 971) are shown the results of the Viva Voce Examinations held at various centres during the current year.

The Commercial subjects included Book-keeping, Accounting, Banking, Shorthand, Typewriting, Economic History and Theory, Précis-writing, Theory and Practice of Commerce, Commercial Law, Company Law (added to the list this year), Economic Geography, Arithmetic, Handwriting, etc., Commercial Correspondence, etc., and English, French, German, Spanish and Italian. The other subject of examination was Music, divided into Rudiments of Music and Harmony.

The Society this year awarded thirty-two Silver and forty Bronze Medals, the former in the Advanced Stage and the latter in the Intermediate. It also gave away money prizes to the value of £104, besides the prizes, amounting to £40, provided annually by the liberality of the Clothworkers' Company.

In addition to these medals and prizes, the Scholarship offered by the London School of Economics was duly awarded for the Theory of Economics.

The Clothworkers' Company's prizes have been offered under various conditions since 1891. This year the sum of £40 was offered for prizes in Theory and Practice of Commerce, Commercial Law, Economic Geography, and Spanish.

While it is probable that the offer of medals

and prizes does not very largely affect the numbers entering for any given subject, it seems certain that it does attract a better class of student, and so helps in keeping up the general standard of the examinations. The awards are very highly valued, and are a great encouragement to those who win them; and there can be no doubt that if, as may very likely be the case, the Council are compelled by financial pressure to discontinue them for a year or to reduce their number, their absence will be a bitter disappointment to many of our best and most earnest students.

Certain alterations were made in the syllabuses for various subjects. These alterations, like those made last year, were intended to meet as far as possible the views believed to be held by the teachers of classes in those subjects, and also to bring the examinations into greater harmony with the character of the commercial instruction now being given in the schools under the Board of Education.

No new subjects were added, but Accounting and Banking were separated, and now form two subjects instead of being combined in one. Company Law has been made into a separate subject, instead of being included in Commercial Law. Commercial History was separated from Commercial Geography, and forms a separate subject under the title of Economic History. The subject of Economics is now restricted to the Theory of Economics, and is so entitled.

Certain other alterations were made in the syllabuses of the modern language subjects. In all these subjects certificates are now granted in the two lower stages on a general knowledge of the language alone. In Stage III. the candidates are expected to specialise to a certain extent, and must show a literary, technical, commercial, or scientific knowledge, as well as a good general knowledge of the language.

It was always a source of complaint that candidates had to wait a long time before they could know the results of their examinations. A new system of publication of the results of the examinations has been started this year, and has been much appreciated. The candidates fill in a counterfoil attached to the paper on which they do their work; on these counterfoils the result of the examination is marked, and they are returned to the centres as soon as possible. By this means candidates are informed of the result of their examination some weeks sooner than in former years, when they had to wait until all the papers had been reported on and classified, and the printed results issued.

The results of the March examinations were sent to the centres concerned, the Advanced on April 24th, the Intermediate on May 12th, and the Elementary Stage on June 1st.

The results of the May examinations were issued—the Advanced Stage on June 29th, the Intermediate on July 16th, and the Elementary on July 27th. The complete list of all the results, classified under localities, was published early this month.

It may be interesting to compare the number of male and female candidates who obtained certificates at the current year's examinations. Of the 15,760 candidates who passed, 8,330, or 52·85, were males, and 7,430, or 47·15, females. Among the candidates from provincial centres the proportion of males is larger, there being 54·22 per cent., while females are 45·78. In London the proportions go the other way, and the females are more numerous, in the proportion of 52·50 to 47·50. This is due to the fact that the private institutions in London sent in 730 young women and 400 young men. In the London County Council Institutes the males are in a larger number, there being 1,120 to 950 females. It may be added that the Scotch centres also show a larger proportion of females. No precise calculation has been made for any previous year, but it is probable that three or four years ago the proportion of females was under 15 per cent. of the whole.

As has been the case for many years past, the numbers in Book-keeping are still ahead of those in any other subject, though as compared with last year—when there were 11,883 candidates, by far the highest number examined in any year—the figure has been sadly reduced, since there were only 8,960, a falling-off of not far short of 25 per cent. The proportional falling-off is greatest in the two higher stages, there being, as compared with last year, a diminution in Stage III. of 779, in Stage II. of 1,028, and in Stage I. of 1,116. None of the other large subjects show the same amount of loss as this. Up to last year the growth in this subject had been continuous for the past five years, and we have to go back to 1910, when 9,714 candidates were examined, to approach the level of the present year. In the Advanced Stage the examiner notes that on the whole the work submitted was creditable. The first-class certificates show an increase of 1·74 per cent., the second-class

a decrease of 2·39 per cent., and the failures an increase of 0·65 per cent. In the Intermediate and Elementary Stages the work was also creditable, but did not show any advance on previous years.

The next most popular subject was Shorthand. In this there was a falling-off of 1,276, there being 6,539 candidates examined this year as compared with 7,815 last. It will be noticed that the proportion is not nearly as large as that in Book-keeping, amounting to about 16 per cent. The examiner remarks that the results in all stages do not indicate any very marked variation on those of previous years, and they have quite come up to his expectations. In all cases the percentage results show an improvement upon the work of last year, when it appears probable that the papers set were a little above the usual standard of difficulty, and it may be this fact, rather than any definite improvement, which causes the rather larger proportion of successes. The standard in this subject has always been kept rather high, and, as remarked last year, a certificate in the first class of the Advanced Stage has always been looked upon as a certain passport to employment. The examiner considers that the work generally is quite up to the level of previous years. He also notes that the results in the two examinations correspond satisfactorily. His remarks upon the mistakes made by the candidates should, as usual, be carefully studied both by students and teachers. Indeed, both candidates and their teachers may very well be recommended to read carefully the reports of the examiner for the last few years.

The entries in Typewriting have kept up rather better than in the two subjects previously mentioned. This year there were 2,566, and last year 2,806, a falling-off of 240. The proportion of loss is highest in the Advanced Stage and smallest in the Elementary. The examiner considers that, taken as a whole, there was a pronounced improvement both in quality and quantity of the work submitted. As in the case of Shorthand, the examiner's comments on the papers are well worth the study of prospective candidates and their teachers.

It was noted in last year's report that there had been a steady growth in the numbers entering for the very important subject of Arithmetic. The increase naturally has been stopped for this year, but the falling-off is not excessive—419 as compared with last year, or 13 per cent. The actual numbers are 2,806 for the current year, and 3,225 for 1914. The diminution is spread over all three stages. So far as can be judged from the percentage results, the character of the papers in Stage III. shows an improvement, and of those of Stage II. practically no change. In the opinion of the examiner there is on the whole an improvement in all stages. Special attention may be drawn to the solutions which have been worked out by the examiner for the papers set at both the March and May examinations.

English is one of the very few subjects which show an actual increase in the number of papers worked at the present year's examinations. Last year there were 743, this year 816—a total increase of 73. This increase manifests itself in Stages III. and I., and there is a very small falling-off in Stage II. The work on the whole was, in all three stages, according to the examiner's opinion, satisfactory, and it looks as if there is a slight advance on last year. There is certainly no falling-off, though the general average is kept down, especially in the Elementary Stage, by a number of candidates whose work was extremely feeble. On the other hand, this same stage showed a considerable number of candidates whose work was really very good. The very full comments by the examiner on all the papers set are well worth a careful study.

As previously noted, there was a certain rearrangement of the subjects dealing with Economics, and instead of having a single subject under the title of Economics, and another under Commercial History and Geography, the whole subject has been divided into three—Economic Theory, Economic History, and Economic Geography. With regard to the last mentioned Economic Geography—there is a certain diminution, as there were 246 candidates, compared with 282 last year—a total loss of 36. Having regard to the fact that Commercial History was taken away from this subject and made into a subject of its own, this falling-off cannot be considered as very serious. It is, however, deplorable that so few candidates as 18 should come up for the examination in the Advanced Stage, and only 38 in the Intermediate Stage. The entry of 190 for the Elementary Examination cannot be considered as unsatisfactory, though it is a matter for regret that more attention should not be given to this very important subject in the teaching institutions from which the Society's candidates are for the most part drawn. As regards Stage III., the examiner considers that the work was poor and generally

inferior to the standard of that done by candidates in the Intermediate Stage. In the latter stage the work of those who entered for the March examination was inferior, but in May the work was a great deal better. In the Elementary Stage the work of the candidates was about normal.

For Economic History 24 candidates entered —14 in the Advanced Stage and 10 in the Intermediate. For Economic Theory 103 entered—47 in the Advanced and 56 in the Intermediate Stage. For the two subjects together we get a total of 127, which compares with 158 who entered in 1914 for the one subject of Economics; there is thus a falling-off of 31. As regards Economic History, the examiner considers that the general results were good. In the Advanced Stage the general level reached was distinctly good, and the papers showed evidence as a rule of careful and intelligent study. In the Intermediate Stage the general quality was satisfactory, and there were a few papers of great merit. As regards Economic Theory, in the Advanced Stage a little less than half the papers attained a high level, both for knowledge of the subject and ability in stating that knowledge. The other half did fairly well, though in some instances they did not avoid failure by a large margin. The number of total failures was small in the Intermediate Stage, a fair proportion showed a good knowledge of the subject, and the candidates wrote with vigour and intelligence about it. The number of failures was not great, but many candidates only just reached a satisfactory level.

The entries for the subject of Précis-writing have of late years shown a decline in numbers, though there was an increase over some previous years in 1914. This year there were 138 candidates—a falling-off of 60 on the 198 of last year, or 33 per cent. Although the numbers are not very large, this is a very heavy proportionate decrease. On the whole the standard appears to be much the same as that of recent years, and it is certainly not any better.

The number of candidates entering for Commercial Law was no doubt affected by the splitting of this subject up into two, and the consequent addition of Company Law. 184 entered for the first-named subject, and 104 for the second, 288 altogether. This shows a small falling-off on the 308 of last year. As regards Commercial Law, the examiner considers that the average merit of the papers worked reached about the same level as in previous years. In Company Law the papers were purposely made rather easy, and it may be hoped that the standard may be raised in future years. As regards both subjects the attention of the candidates may be drawn to the examiner's comments.

The subject of Accounting and Banking has this year been cut in two, and separate papers were set in Accounting and in Banking. 384 entered for the first-named subject, and 125 for the second. This total of 509 shows an increase of 21 on the 488 candidates who entered for the one subject in 1914. Having regard to the general depression this year this may be considered a very satisfactory result, and it quite justifies the alteration in the syllabus. In the examination in Accounting, the examiner reports that some of the work submitted was excellent, and as a whole the average merit attained was creditable. In Banking the examiner considers that on the whole the work sent in was satisfactory, though some few candidates entered for the examination without adequate preparation.

233 candidates entered for the examinations in the Theory and Practice of Commerce—83 in the Advanced, and 150 in the Intermediate. This subject offers a rare example of an increase in the number of candidates. The total increase over the 154 of last year was 79—72 in Stage II. and 7 in Stage III. In both stages the examiner finds that there was a small proportion of first-class papers, and, as regards the May examination in Stage II., there was too large a proportion of failures, though in March the number of failures was slightly less than last year.

The popularity of the examination in Commercial Correspondence and Business Training is shown by the fact that it also shows an actual increase in numbers. The number of candidates, 606, is indeed the highest yet reached. In 1913 there were 603, and last year the numbers dropped a little to 588. The examination in this subject is in the Intermediate Stage only, and candidates capable of taking a higher certificate may be advised to study for the examination in Theory and Practice of Commerce. At the same time it is quite clear that a large number of young students appreciate the easier test. In the opinion of the examiner, the papers generally are of much the same character as last year, and the percentage results show a slight improvement in the first class, a falling-off in the second, and an increased number of failures.

In the corresponding subject in the Elementary Stage—Handwriting and Correspondence there were 1,666 papers worked, a falling-off of 246 on the 1,912 of last year. It may be taken that these numbers show the considerable popularity of this subject. On the whole the papers this year were, in the examiner's opinion, a little better worked than last year.

The number of candidates in French compares not unfavourably with that of last year, though there is a falling-off of 170, there having been 2,784 candidates examined in the current year and 2,954 last year. The falling-off appears in all three stages. For some reason which it is difficult to suggest, the number of entries for French has not shown of recent years the same tendency to increase as is manifested in most other subjects, though it has always been one of the most popular subjects, and has regularly attracted a large number of entries. In 1911 there were 3,647 papers worked, and there has been no entry like this in any year since. In all stages there was a distinct improvement in the character of the work sent in. The examiner reports the work in Stage III. as excellent, and better than last year. In Stage II. there were some first-class papers, and a smaller number of failures, while in Stage I. there were more good papers than usual.

That there should have been a heavy falling-off in the German results is by no means surprising, and perhaps it is a matter for no great regret. Indeed, it had been a question for consideration whether, under existing circumstances, it was desirable to hold any examination in German at all. On the whole, however, it seemed better to let matters take their usual course. There is no doubt that in the future the commercial value of the German language will be very much less than it was before the war; but whatever the ultimate issue may be, a knowledge of the language must be valuable, and if there is no particular reason to encourage its study, on the other hand it does not seem wise to restrict existing facilities. The total number of German papers, 462, was a little more than half that of last year, 826, which again was less than the previous year, there having been a steady falling-off in the number of entries since 1912, previous to which year there had been for some time a regular increase. In Stage III. both in March and May the work was exceptionally good. In Stage II. the improvement was not so marked, and in Stage I. the general average was higher than it had been for some years.

The number of entries in Italian was inconsiderable, not very much above half the number last year—there were only 44. Last year there were 76. The entries for this language are never very numerous; but as a rule the work is fairly good, and this in the examiner's opinion was the case this year on the whole, while the excellence of the papers in the Advanced Stage was noticeable. Since the examinations were completed the Society has lost the services of Professor Luigi Ricci, the accomplished Italian scholar, who had acted as the Society's Examiner in Italian since the year 1904.

The number of candidates in Spanish kept up moderately well, there being 227 as against 355 last year. They were equally divided among the three stages—74 in Stage III., 76 in Stage II., and 77 in Stage I.

No other examinations were held in any of the other modern languages in the Society's list. For some years past the Society has expended a good deal of money in trying to encourage the study of the less popular languages, and has held examinations in Russian, Danish and Norwegian, Hindustani, Japanese, Chinese, Arabic, Swedish and Dutch. The old rule was that no examination would be held in any subject for which less than 25 candidates presented themselves, but this regulation was ignored in the hope that the numbers would increase if the study of the languages could be rendered more popular. As a result, taking the last six years, only 216 candidates entered, at a cost of about £350, and this, after deducting the £27 paid by the candidates in fees, meant a net loss of £323, or say £1 10*s.* per candidate. It was therefore determined to enforce the strict rule, and as the entries in the above-named subjects were very few, no examination was held this year in any of them.

Inasmuch as special efforts are being made by the Education Committee of the London County Council to encourage the formation of the study of Russian, it is to be hoped that a sufficient number of candidates may be forthcoming to justify the holding of an examination. It may be added that even if quite the stipulated number do not enter, the Society will probably make an exception in this particular case. Since it may be considered certain that our business relations with our Ally will develop in the future, a knowledge of Russian will be a valuable asset to those entering a commercial career.

For the Viva Voce Examinations held this year in Modern Languages 428 candidates entered at London centres and 25 at Manchester. Last year examinations were held also at Liverpool, Birmingham, and Bristol, but at these centres no entries were made this year. This number shows a heavy falling-off as compared with last year, when there were 628. These examinations were started in 1902, when 280 candidates were examined. The numbers rose to 681 in 1905; after that there was a small diminution, the numbers varying slightly year by year, and falling to 583 in 1911, then they increased again to 688 in 1913, and this was the highest point yet reached. Examinations were held this year in French, German, Spanish, and Italian. The numbers were: French, 339; German, 79; Spanish, 25; Italian, 10. Table L (page 971) gives in detail the results of this year's examinations.

The examiner in colloquial French states that, as usual, the results of this examination were very satisfactory and the proficiency of the candidates most praiseworthy. The presence of the Belgian refugees in our midst has seemingly been turned to good account. The work in German was good, though naturally enough the entries in this subject were not numerous. On the whole, the examiner says the work was excellent, and a large proportion of candidates earned distinction. Very many of the candidates displayed a really remarkable power of easy and fluent speech. The results of the Spanish and Italian examinations were much of the same character as in previous years.

These examinations are held at any of the Society's centres where the necessary arrangements can be made, at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and is so arranged as to test efficiency in colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners receive a certificate of having passed with distinction.

The examinations in Rudiments of Music and Harmony were carried on as usual at the same time as the Commercial examinations, and the results appeared as part of the results of the Intermediate Stage. The total number of candidates was 509, a decrease of 78 on last year's figures. This falling-off has been practically continuous for the past six years, and the present year is the lowest for the past ten. The figures are 587 in 1914, 617 in 1913, 688 in 1912, 691 in 1911, 619 in 1910, 699 in 1909, 716 in 1908, 641 in 1907, and 637 in 1906.

In Rudiments of Music 254 candidates presented themselves; last year there were 342. In Harmony there were 255, as compared with 245. Of the 254 candidates in Rudiments of Music, 202 passed and 52 failed. Of the 255 candidates in Harmony, 190 passed and 60 failed. The results do not differ very much from those of recent years, the proportion of successes and failures being singularly constant.

There were no Practical Examinations in Music this year, these examinations having been discontinued after 1914. An account of the history and progress of these examinations will be found in the Report on the Examinations of 1914, and in the Council Report for the Session 1914-15.*

The special annual examination in Shorthand for soldiers has not been held this year. It was started in 1907 at the request of the Army Council, and has been held every year since. In 1907 there were 40 candidates; in 1908, 84; in 1909, 60; in 1910, 66; in 1911, 61; in 1912, 45; in 1913, 51; in 1914, 57.

The Examination Programme for 1916 was issued on the 4th inst. In it will be found the fullest possible information about the examinations, a syllabus of each stage of each subject, and the papers set in May, 1915.† The attention of both teachers and students may be drawn once more not only to the syllabuses but also to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially are earnestly recommended to study these remarks, as they ought to be guided by them in the instruction they give to their pupils.

The regulations for the Examinations in the Theory of Music, and those for the Viva Voce Examinations in Modern Languages, are also given at full length.

* See *Journal*, Vol. LXII. p. 919 and Vol. LXIII. p. 715.

† The price of the Programmes for 1914, 1915 and 1916 is 4*d.* each, post free 6*d.* Copies can be obtained on application to the Secretary of the Royal Society of Arts, Adelphi, London, W.C. Programmes containing the papers set from 1905 to 1912 can also be obtained (price 3*d.* each year, post free 4½*d.*). The papers set in March, 1915, are not included in the 1916 Programme. They are printed in a separate pamphlet, price 2*d.* (post free 3*d.*). The regulations and syllabuses for the present year can also be had separately (without the papers), price 1*d.*, by post 1½*d.*

SEA ROUTE TO SIBERIA.

The *Times* publishes some interesting particulars relating to the arrival at Grimsby of the steamers "Haugastoel" and "Eden," chartered by the Siberian Steamship Manufacturing and Trading Company (Limited), which have brought cargoes of butter, hemp, flax, and other produce, valued at £350,000, from the Yenisei and Obi districts of Central Siberia. An account of this enterprise appeared in the *Journal* of February 12th, 1915 (p. 254), and its successful accomplishment may be considered an important event in the history of the attempts to establish a sea route to Siberia *via* Norway and the Kara Sea.

The practicability of this route was first demonstrated by Captain Wiggins, who in 1874 sailed from Dundee in the Arctic yacht "Diana," proceeded up the Obi Gulf, cruised over towards the mouth of the Yenisei River, and returned home in safety after spending some eight weeks in the Kara Sea. This voyage was followed by several others, and in 1880, and again in 1895, Captain Wiggins read very interesting papers, describing his discoveries before the Royal Society of Arts.

The work of which Captain Wiggins was the pioneer has now been taken over by Mr Jonas Lied, of the Siberian Steamship Manufacturing and Trading Company He has taken out vessels for three years in succession, but the last expedition of the "Haugastoel" and the "Eden" point to further and more important developments. Owing to the Siberian Railway having been taken over by the Russian Government exclusively for war purposes, an outlet for Siberian commerce by sea has become a matter of urgency. As much as 150,000,000 poods of wheat are held back in the interior, and enormous quantities of butter, hemp, flax, linseed, and other raw produce are being stored at great expense. Mr. Lied is already making preparations for another expedition next year on a far larger scale than anything hitherto attempted. He proposes to send out between twenty and thirty ships.

One very important result of this year's enterprise, says the *Times*, has been to establish the possibility of making use of the Obi River as well as the Yenisei. The Obi runs through the most fertile district of Central Siberia. In previous years Mr. Lied left it outside the scope of his operations, owing to the shallowness of the waters which had to be traversed at its mouth to meet the river craft. On experiment, however, this year Mr. Lied found that the difficulties had been exaggerated, and that a steamer of 3,100 tons was able to take a full cargo there. The Yenisei needs, to bring produce down to its mouth, a much larger fleet of river boats, the expense of which, in view of the war, the Russian Government is unwilling to incur. The present boats, about forty in number, are sufficient only to charge two or three sea-going steamers. On the Obi, however, there are 350 river steamers and 650 barges, with a capacity of up to 3,000 tons each. This fleet is capable of bringing down 500,000 tons of goods a year.

Increased experience of the Kara Sea route has resulted in a marked shortening of the time taken by the voyage. In 1913 the "Correct" was twenty-three days on the way from Tromsö in the north of Norway, the last port of call, to the Yenisei. This year the voyage both there and back was accomplished in nineteen days. The main difficulty in the past has been the prevalence of ice in the Kara Sea, and it has been overcome by the use of wireless telegraphy, as was explained in an article in the *Journal* of December 12th, 1913 (p. 79). The Russian Government has erected three wireless stations in this region, which correspond with a station at Archangel. The first two stations command the two straits which give entrance to the Kara Sea, and approaching vessels can be informed by wireless which strait is freer from ice and what are the conditions beyond.

Mr. Lied considers that it is now possible to guarantee a through passage every year "Central Siberia," he adds, "is the richest country one can imagine. It only wants communications. English people, I think, hardly realise what the resources of Siberia are. I daresay they will be surprised to hear that it has populous cities- Omsk, Tomsk, and Irkutsk, each with 130,000 inhabitants or more—where you will find people going to the theatre in evening dress."

ENGINEERING NOTES.

Artistic Bridge Building in America —The bridge recently completed at South Bend, Indiana, across the St. Joseph River, from Leeper Park on the south side to the north shore drive, was designed with special attention to external appearance because of its location. Bedford stone, smooth finished and laid in non-staining cement mortar, was used for facing the entire bridge and for the handrail. An elliptical curve was adopted for each of the three arch spans of small rise, and the resulting outlines give a very satisfactory appearance. Work was begun on this bridge on August 20th, 1914, and just about five months later street car tracks were laid, and practically all the construction, except sidewalks and paving, had been completed. The structure is 300 ft. long and 70 ft. wide between spandrel walls, and contains approximately 7,000 cubic yards of concrete. The foundation soil consisted of sand, gravel, clay, and quicksand in the various locations, hence it was necessary to drive piles from 25 ft. to 35 ft. long about 4 ft. on centres under all piers and abutments, in order to eliminate any danger from washing out of the quicksand at the foundation of the south pier; the 18 ft. steel piling used for the coffer dam was driven down to a point 12 ft. below the footing. The centre arch has a clear opening of 116 ft. and a rise of 16 ft. 8 in., or about one-

seventh of the span; the two side arches are 80 ft. clear span and 14 ft. 6 in. rise. The flatness of these arches was decreased by using a roadway grade line on a vertical curve, with a rise of 4 ft. at the centre of the bridge. The piers are 12 ft. wide and 87 ft. long, and extend 16 ft. below the springing lines of the arches. They were designed to withstand the unbalanced load of the longer arch, by making the footing 6 ft. wider on the side opposite the large arch. The solid arch ring of the 116-ft. span is 2 ft. 4 in. thick at the crown, 4 ft. at the haunches, and 8 ft. 6 in. at the piers; the arch rings for the 80 ft. side spans are 1 ft. 10 in. thick at the crown, 3 ft. 3 in. at the haunches, and 6 ft. 6 in. at the abutments. These arch rings are reinforced at both intrados and extrados with deformed bars spaced 12 in. on centres and extending well into the piers and abutments. Lacing bars of ½-in. rods connect the main bars, which are also tied together by ½-in. rods running at right angles to them and spaced about 1 ft. apart. The spandrel walls were built of concrete, reinforced with ⅞th bars, and placed behind the Bedford stone facing already mentioned. After the stones were laid up they were coated on the back with a heavy coat of waterproofing, including a second coat of asphaltic paint, special care being used at the joints. The same treatment was given to the back of the arch rings and the spandrel walls, and no discolouring whatever has developed. The arch rings were designed for a live load of 300 lb. per square foot over approximately one-half of the span; the line of pressure for this loading was found by the elastic theory to be within the middle third of the joints for the entire arch. The dead load was assumed at 150 lb. per cubic foot for concrete, 100 lb. per cubic foot for earth embankment, and a 100 lb. per square foot for the pavement. Concrete, composed of 1:2½.4 mixture of Portland cement, washed sand, and crushed stone, was used for the arch rings, and for the piers, abutments, and spandrel walls, the proportions were 1:3 5. The contract price for the bridge was £20,500. The above details have been abridged from the *Engineering Record* of New York.

Oil and Concrete.—It is reported that the Director of the United States Office of Public Roads has found that concrete may be made damp-proof by mixing mineral oil with the materials, and that the presence of the oil does not reduce the tensile strength or substantially lessen the compressive strength. The oil is added to the matrix after the latter has been well mixed, and after thorough incorporation traces of the oil disappear—where is not stated. Perhaps this disappearance is the explanation of the apparent anomaly, and the concrete maintains its normal strength in spite of the oil, deriving some compensation from the additional mixing. That the admixture of oil would tend to oppose the passage of moisture is not surprising, but it is strange that the strength of the mass should not, at the same time, be lessened. The addition of the oil seems to delay the setting of the concrete, but not the rate of increase in strength.

A New Steel Plant in Australia.—On April 2nd, in Engineering Notes, we remarked on the first manufacture of steel in Australia. The operations began recently by the "blowing in" of a 350-ton blast furnace. One blast furnace, three open-hearth furnaces, and a combination structural steel and rail mill have been completed, and sixty by-product coke ovens are under construction, at Newcastle, New South Wales. The plant owned and operated by the Broken Hill Proprietar (Limited) of Australia, which company controls large iron-ore deposits in South Australia. The expert steel workers have been brought from various steel centres in the United States, and are, in general, under a three years' contract.

The Manufacture of Patent Fuel.—An important industry of South Wales that has made great progress during recent years, we hear from a correspondent of the *Times*, is the manufacture of patent fuel. This substance, known on the Continent as briquettes, has hitherto been composed chiefly of small coal, with a binding agent, usually pitch, made into blocks of various sizes and shapes. The magnitude of the industry may be gauged from the fact that in Germany over 20,000,000 tons per annum are produced, while in France, also, there is a very large output. This country as yet ranks third with less than 2,000,000 tons per annum, made chiefly in South Wales. The production in the last few years has, however, more than doubled. While possessing many advantages, patent fuel has had to contend with one great obstacle to its use as a naval fuel. The mixture of pitch causes it to give off considerable quantities of smoke, and for many years experiments have been made to find a binding substitute that would make the resulting fuel as smokeless as the best Welsh coal, without reducing its high efficiency. For this purpose, flour, glucose, molasses, and many other substances have been tried with only partial success. During the last eighteen months, however, some important experiments have been carried on under the control of Mr. D. A. Thomas in conjunction with Mr. H. J. Phillips. The system is to produce blocks of nothing but pure coal by forming, under very great pressure, powdered coal into blocks of suitable size and shape. It is claimed that the blocks thus made are weatherproof and are not more smoky than coal. It is understood that steps are being taken to establish works in South Wales to manufacture this new class of patent fuel on a commercial scale.

Engineering Representation Abroad.—In a paper contributed to the Institution of Electrical Engineers, Mr. Pollard Digby, in reviewing the

question of commercial warfare which must ensue on the attainment of military victory, makes a plea for scientific and technical commissioners. After the war capital will be very scarce, and exports of capital in the form of, say, engineering machinery and railway plants to neutral markets will probably be on a greatly reduced scale. The loss of food-getters will impose on the remainder of the community concerned the necessity of greater efficiency of production or of longer hours at the desk, foundry, lathe, and loom. Possibly it will involve both. The organisation of industry, particularly with reference to oversea markets, is important and the better the industrial organisation of any manufacturing nation, the sooner will be the recovery from the aftermath of the war. In many things before the war Germany did a great deal which we would have done well to emulate. Trade Commissioners and commercial attachés have been appointed, and it is with no idea of belittling the useful work that they have done that the author urges the selection of an entirely new type of official representatives to perform the duties of Technical Commissioners. They should be specialists acquainted with the needs of distinct industries and possess the necessary gifts of tact and literary expression. The professional status of a Technical Commissioner, say, in engineering, should be at least the equivalent of full membership of one or more of the institutions most closely concerned in his work. Before proceeding to take up his post, the newly appointed Technical Commissioner should have ample opportunity of conference with representatives of the industry concerned with his sphere of work, both as regards their selling and their technical departments, and methods of manufacture. At stated intervals he should return to England to confer with those concerned in his work. Mere exhibitions of German articles in London with particulars of the wholesale and retail prices, though good in their way, will not suffice. We need representatives with technical experience and foresight, studying conditions in the markets which we seek to supply.

Electric Car Heaters for Cold Weather Concreting. By putting electric car heaters to the novel use of warming concrete during construction in cold weather, the Salt Lake and Ogden Railway was able to complete over half a mile of street track last season. The work consisted primarily of 7-in. 80-lb. T-rails on box girder sleepers supported by a concrete base. The concrete was poured through chutes direct from the mixer to the track. Electric car heaters were then installed at intervals of 10 ft., and connected ten in series on a 720-volt circuit. Canvas was stretched over the green concrete, and the heaters were placed in circuit with the trolley wire by means of a fishpole connection. In this way the entire mass was kept warm until the concrete had set.

OBITUARY.

CONRAD THEODOR VAN DEVENTER.—The Netherlands statesman, Dr. C. Th. van Deventer, who died on September 27th, was well known in Anglo-Indian circles, and took a great interest in British colonial developments. He had been a member of the Royal Society of Arts since 1909, and, before the war, he had promised to read before the Society a paper on the Dutch Colonies.

At the age of eighteen he entered Leiden University and in 1879 became a doctor of law, after writing a dissertation on the question: "Are our Colonies, according to our Constitution, part of the Realm?" In this same year he went to Delft, to qualify for the Dutch Indian Civil Service; in 1880, at the age of twenty-three, he passed the required examination, and went out to Java

After a couple of years' service as clerk to a court of justice, he entered a firm of lawyers and made his fortune, returning to Holland in 1897. It proves his versatility that, upon his return to the Netherlands he became the musical correspondent of a Netherlands-Indian paper. This, and the writing of numerous able and lucid articles on colonial subjects for leading Netherland reviews and papers, fully occupied his time, and in addition he became one of the editors of the Netherlands monthly review, *De Gids*.

In 1904 the Netherlands Minister of the Colonies invited him to prepare and write a report on "The Economical Condition of the Native Population of Java and Madura," and for this work a knighthood of the Order of the Netherlands Lion was conferred on him.

In 1905 he was elected a member of the Second (popular) Chamber of the States-General, but lost his seat at the General Election of 1909. In 1910 the Government sent him to Brussels as chairman of the select committee representing the Netherlands colonies at the exhibition. In 1911 he was elected a member of the First (upper) Chamber of the States-General; in 1912 he revisited the Netherlands East Indies and travelled all over the colonies; and in 1913 he was again elected a member of the Second Chamber.

A remarkable part of van Deventer's labours on behalf of the native population was connected with the Kartini schools. Kartini was a Javanese princess, who received the usual training and education of an Oriental girl of such high rank. This, however, did not satisfy her, and when still in her teens she found ways and means to educate herself and emancipate her mind from the traditional Oriental conventionalities. She then wrote a book, in which she explained what had moved her, and expressed the hope that it might be possible to do for other Javanese girls and women what she had succeeded in doing for herself. She came into touch with leading Netherlands personalities, van Deventer being one of them, and

he became the chief organiser of the Kartini Foundation, which by donations and annual subscriptions establishes and runs the Kartini schools for Javanese girls.

GENERAL NOTES.

THE WORLD'S POTASH.—The potash hitherto used in this country has been chiefly derived from the enormous deposits of potash salts which occur near Stassfurt, in the north of Germany. These deposits have been systematically and economically worked, and the trade was so well organised, that German potash, on account of its cheapness, became the almost exclusive source of the potash required throughout the world. The German source being no longer available, it has become necessary to take stock of other sources of supply, and these are considered in "The World's Supply of Potash," a pamphlet just issued by the Imperial Institute. In this pamphlet—which forms, in fact, a miniature encyclopædia of its subject—both the old and new sources of potash are described so far as details are available. Certain of those will probably only be utilised so long as the price of potash continues high, but others promise to become active competitors with the Stassfurt deposits, even when prices again fall to their usual level. The chief use of potash, usually in the form of chloride or sulphate, is as an artificial manure, for which purpose over 90 per cent. of the world's output is employed. But potash is also essential for numerous chemical industries carried on in this country, and for the manufacture of the finest kinds of glass, and the present scarcity is having considerable effects on these industries. The increased production of potash in the United Kingdom from kelp and other vegetable sources, referred to in this pamphlet, is now under serious consideration.—*Engineering.*

INDIAN MICA.—The Hazaribagh district is one of the most valuable mica-producing areas in the world. Except for a very small amount from Sweden, all the "ruby" mica comes from Chota Nagpur, and India yields more than half the world's output of mica generally. The country where it is found is of a jungly nature, and this renders observation of the prospecting coolies a difficult matter. These coolies scoop away the earth and find the mica generally at a comparatively small depth from the surface. It is then in irregular lumps, usually not more than 12 to 15 in. long and 6 or 8 in. thick. This is split into scales or laminae. Large sheets are the most valuable, and a piece 30 in. square would probably fetch 100 rupees. When split up into sheets it is classified according to size and packed in what are known as books. It is then ready for export. According to the *Pioneer Mail*, however, it is very seldom that a large sheet finds its way to the owners of the land on which it is found. The coolie usually hides it in the ground, and subsequently sells it to an agent. The nearest parallel to what occurs is found in illicit diamond buying in Kimberley and other parts of South Africa. Although the expenses incurred in working mica are extraordinarily small, the business does not pay if no large "books" are obtained. Consequently, if a firm is consistently being robbed of its best finds it naturally fails, and this is the reason for the failure of so many firms.

BUSINESS WITH ITALY.—The *British Export Gazette*, in a recent article, reviews the present and past position of Italy in regard to trade with Great Britain and with the Central Powers, pointing out that the entrance of Italy into the war is Great Britain's opportunity to regain lost trade with this country. To-day, says the *British Export Gazette*, Italy finds herself obliged to seek new sources of supply for goods to the extent of £35,000,000 annually, hitherto obtained from the two Teutonic Empires, and to find new markets for produce and manufactured goods to the amount of £22,000,000. Germany had obtained almost complete control over Italian banking and financial institutions, as, indeed, over almost every industrial and commercial activity. In Italy the feeling is very strong that the bulk of the manufactured goods required should be purchased from the United Kingdom, and the latter encouraged to enjoy once again the very large share of the trade formerly held; but the attention received from the German firms must be accorded by British firms also if business is to be done. German catalogues and price lists were sent printed in Italian, with decimal coinage, weights and measures, and correspondence from Germany was conducted in the Italian language, requests for further information were immediately replied to, and all orders taken or given were executed with promptness, while German commercial travellers penetrated even to the remote country districts. Now that Italy has entered into the conflict, she will not be requiring for ordinary domestic consumption all that she required while she remained neutral; it is rather the future that is to be prepared for, the shaping of things now, in view of developments after the war; the market should be wooed and appropriated as far as possible, the probability being that when peace is signed the prejudice against everything Teutonic will remain bitter for years, and German goods will not be bought in Italy if the same class can be obtained from other countries.

CANADIAN COPPER FOR SHELLS.—It is announced in Ottawa that arrangements have been completed under which, for the first time, zinc and copper required for the manufacture of shells will be both produced and refined in Canada. Hitherto Canadian manufacturers have depended entirely for their supply of these materials upon American manufacturers.

FRIDAY, OCTOBER 22, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS IN ENGLISH FOR BELGIAN REFUGEES.

In response to several applications, the Council have decided to hold an examination in the English language for Belgian refugees, provided a sufficient number of candidates enter. The paper would be specially adapted to the needs of foreigners, for whom the present examination in English is obviously unsuited.

It is proposed that there should be an Elementary paper, and also, if a sufficient response is made, one in the Intermediate Stage. It appears improbable that there will be many candidates capable of taking an Advanced Stage paper, but if a sufficient number apply one may be set in this stage also.

It is proposed that the examination should be held, under the usual conditions, either in the April Examinations (April 10th–19th), or in the May—June Examinations (May 29th—June 7th).

Intending candidates should apply to the Secretary of any of the Society's local Examination Committees. A list of these can be obtained at the Society's House.

SCIENCE IN THE WAR AND AFTER THE WAR.*

Turning to the applications of science in the war, we can mention four chief departments of it under the headings chemical, mechanical, electrical, and physical, which cover such appliances as high explosives, aeroplanes and dirigibles, submarines, wireless telegraphy, and range-finders. I shall not attempt to discuss the details of a fraction of all these applications, but just touch briefly on two departments which happen to have occupied my own attention during the vacation, viz., range-finders and wireless telegraphy from aeroplanes.

An extremely important matter in all war with projectiles is to ascertain the exact distance of the objective, whether it be ship or gun or building. The range of the projectile depends on the angle of elevation of the gun and the character of the ammunition and several other factors.

The proper setting of the gun can, of course, be determined by trial shots, but the larger the gun the more expensive this process and the more necessary not to let the enemy know anything until a shot or shell falls exactly where it can do most damage to him.

Range-finders have for their object to determine this distance by some optical appliance. They are divided into two classes: first, prism, or base range-finders, and, secondly, subtend range-finders. We can explain the principle of these by reference to our eyes and the method by which we roughly judge the distance of an object. When we look at an object the optic axes of the eyes converge on it, and by long practice we are able to appreciate the inclination of the axes. The centres of the eyes are about $2\frac{1}{2}$ in. apart. Hence we have a very short-based isosceles triangle, but we are enabled by our muscular sense to give a rough guess as to the angles at the base, and practically to infer something about the length of the triangle. Again, we do it in another way by estimating the relative sizes of the image of known objects, such as a man or house or other thing which is formed on the retina. Another thing which assists us is the amount of detail we see in the object looked at.

The range-finders used in war are only more exact applications of the same principles. One of the most accurate is that of Professors Barr and Stroud. This is a base or prism range-finder. It consists of a tube varying from half a metre to two metres, about 6 ft. in length. At the ends of this tube are two totally reflecting prisms, which receive rays from the object and send them down the tube. At each end of the tube is an object glass, which forms an image which is received on a peculiarly cut prism at the centre and by an eye-piece. The arrangement virtually forms a sort of double telescope corresponding to two eyes set 6 ft. apart. When the observer looks into the right eye-piece he sees a field of view which is divided into two parts, one produced by light coming into one object glass, and the other by that coming

* Extracted from the introductory lecture delivered at University College, London, on October 6th, by Professor J. A. Fleming, F.R.S.

in at the other. If the object seen is a mast, say, of a ship, it appears broken in two parts. The observer can rectify or bring into agreement these two parts of the image by moving to or fro in the tube a thin prism. The position of this prism is read off on a scale seen with the left eye-piece. This scale shows the distance in yards of the object.

Thus on board our battleships a range-finder of this kind is placed in one of the fighting-tops on the masts, and the observer looking at a distant ship can in a few seconds move the prism, adjust the two parts of the image to agreement, and read off the range. He then sends down the range by telephone to the gun-layers. Thus in the battle of the Dogger Bank, and in that of the Falkland Islands, firing by our battleships began at about 17,000 or 18,000 yards. The range-finder would thus be continually sending down the ranges 20,000, 19,000, 18,000 yards, etc., and the gunners would keep the object vessel in sight and fire when the command was given as the known range of hitting was reached.

The same principle is applied in a smaller instrument for military use, called the Marindin range-finder, invented by Major Marindin, only in the latter instrument the means adopted for bringing the two parts of the field of view or image into agreement are by a movement of one of the prisms.

The Barr and Stroud range-finder is a very accurate instrument, and will determine ranges up to 20,000 yards, or about 12 miles, with an accuracy of 50 to 100 yards.

In the next place there are range-finders called subtend range-finders, which depend on the measurement of the size of an image of a known object. When we look at an object either with the eye or with a telescope at different distances, it appears to be smaller the farther away we are from it. In the case of the eye we have no means of measuring accurately this variation in size except by comparing the apparent size of the distant object with some near object the size of which is known. Hence judging distance by the eye requires long training, as all sportsmen, sailors, and travellers know.

Moreover, we are apt to be deceived as to the apparent size. Ask anyone, for instance: How large appears the full moon? Many people would say, As large as a shilling—meaning that it has the same apparent angular magnitude as a shilling seen at 10 in. or 1 ft., which is the usual distance we hold a book or paper when reading.

But now, if you try the experiment, you will find that the full moon is covered by a very small pencil, like a pocket-book or dance-programme pencil, held at 10 in. from the eye. In scientific language, the apparent size of the moon is about half a degree, which means that it is covered by an object $\frac{1}{10}$th in. in diameter held 1 ft. from the eye.

A man 6 ft. high would subtend the same angle at a distance of 720 ft. Hence you can tell the distance of a man by ascertaining the distance at which an object of known size, say a pencil, must be held so as just to cover his height. An ordinary pencil $\frac{1}{4}$ in. in diameter held horizontally at arm's length (= 2 ft.) would just cover a man 5 ft. 8 in. high at a distance of 544 ft., or 181 yards. The subtend range-finder works on the principle of measuring the angular magnitude of the object. One way of doing this is to place in the focus of the eye-piece a plate of glass with divisions ruled on it with a diamond. If we know how many divisions are covered by an object of known height at a known distance, we can tell the distance of any other object of known height.

It is very seldom, however, that we do know the exact height of the object, and, moreover, it is very difficult to count up accurately many very small divisions ruled on glass when the object seen is at all dark.

During the vacation I have been turning attention to methods for overcoming some of these difficulties. As these inventions are being submitted to the Ministry of Munitions, I do not think it desirable to go into details as to the methods, but I will tell you the results. I have invented three forms of range-finder—one which is an improved subtend range-finder with which I can find the distance of any object the dimensions of which are known, whether height or width, or any part of it. Also I have invented methods for using two such instruments to measure the distance of objects the dimensions of which are not known. In the second place, I have invented a simple form of base range-finder which measures what is called in astronomy the parallax of any distant object, and hence determines its distance. In the third place, I have devised a simple form of depression or elevation angle meter by means of which the height of any hill, and also the distance of any object from it, or from an elevated position, can be determined by an observer standing at the top of the hill, provided that he can also see two marks placed at the base in line with the point of observation on the hill and at a known distance apart. These instruments are simple and inexpensive to construct, and give an accuracy of measurement quite sufficient to direct rifle or artillery fire or bomb throwing in trenches. One great advantage of my range-finder is that it can be used with a periscope from the bottom of a trench so that the observer need not be exposed at all, but can determine the distance of the enemy's trench by observation on any post of a wire entanglement or stick or rock or anything with a sharp outline. Another principle which may be applied in making a range-finder, which I have also done in my instruments, is to observe the variation in the size of an object as seen in a small telescope by moving away from it a certain distance. Thus, suppose that a man was seen at a distance of 200 yards, or 600 ft., then his apparent height would be covered by the width of a pencil held about 2 ft. from the eye. Suppose the observer were to approach to half that distance or move in 300 ft., then the apparent size of the man would be doubled. If, however, the man were a mile

away, then moving towards him 100 yards would only increase his apparent height by about 6 per cent. Hence we can determine the distance of an object by finding out how much the apparent size is increased when we move in towards it 100 yards or any assigned distance.

Another marvellous application of science in war is that of wireless telegraphy in connection with aeroplanes and airships as a means of scouting and rapid communication of intelligence.

The difficulties connected with it are, however, considerable, and it has greater limitations than the uninitiated would suppose.

In the case of aeroplanes the first of these is the weight of the apparatus. The military aeroplane is already loaded to its fullest extent. In addition to the pilot and observer and the bomb ammunition, it carries in nearly all cases some gun equipment. Hence any wireless apparatus must be made as light and compact as possible. A wireless transmitter of the so-called spark type involves three elements: (i) some source of electromotive force such as a battery or dynamo, (ii) an induction coil or transformer for creating a high electric potential or pressure, and (iii) some form of condenser or Leyden jar which is charged and then discharged across a spark gap, thus creating rapid movements of electricity called electric oscillations. These oscillations are then caused to create others in a long wire called the aerial wire.

In the case of aeroplanes and airships the source of electromotive force is generally a small dynamo or alternator, which is coupled to the engine, and the voltage or pressure is raised to 30,000 volts or so by a small transformer sealed up in oil in a box. The condenser consists of metal plates sandwiched between sheets of glass or ebonite, and the spark balls between which the spark passes are also enclosed. The weight of the whole apparatus has to be kept below 100 lb., and such apparatus has been designed having a weight of not more than 30 lb. The French use a set weighing about 70 lb. One of the difficulties is to dispose the aerial wire conveniently and safely. It is sometimes made of aluminium and stretched on insulators carried by light supports on the wings, but the difficulty is to obtain in this way sufficient length. One plan adopted is to coil the wire on a reel, which the observer can uncoil and let it float out behind the aeroplane.

The wire must be connected to the reel by a safety catch so as to be released at once if it catches in trees or buildings. By this means an aerial wire of 100 ft. in length can be employed. The observer has near his hand a key by which he controls the spark discharges and so sets up in the aerial wire groups of electric oscillations which create electric waves in the æther, and signal the message in Morse code.

In this manner there is not much difficulty in equipping aeroplanes with transmitters which will send messages thirty miles or so to a corresponding earth station.

These latter are the military portable motor-car or pack stations, the details of which were described in a lecture given here last year on "Wireless Telegraphy in War."

The receiving arrangements used on aeroplanes comprise a head telephone which is worn by the observer associated with some simple form of detector such as a carborundum crystal, aided by which the observer hears the signals sent to him in Morse code as long and short sounds in the telephone.

The noise of the aeroplane engine and that of the rush of air renders this method of aural reception a matter of great difficulty, especially as the messages must be sent in secret code, and the observer must therefore hear every letter distinctly if the message is to be intelligible. Great efforts have been made to devise methods of reception which shall appeal to the eye by a visual signal rather than to the ear, but the exceedingly small electric currents set up in the aerial wire by the arriving waves make this a matter of extreme difficulty, and the problem has not yet been completely solved. There is then the difficulty caused by "jamming." If the signals from an aeroplane are picked up by a hostile station, this latter at once sends out powerful but unmeaning signals, the object of which is to blur and drown out the reception or sending of signals by this aeroplane. Moreover, the sending of wireless signals by an aeroplane reveals its presence to hostile earth stations before it can be seen by the eye.

Hence, wireless telegraphy may be a means of revealing the enemy's scouts, and it involves a certain kind of war in the æther as well as war in the air.

In the case of airships there are other difficulties as well, and it is interesting to note that there are special difficulties in connection with Zeppelins. These aerial monsters are, as everyone knows, constructed with a framework of aluminium, containing in its interior the eighteen or twenty balloons inflated with hydrogen. Now as we rise upwards in the air the electric potential increases rapidly, and if a conducting body at a height gives off water drops or products of combustion, it is rapidly brought to the potential of the air at the place where it is. In the case of Zeppelins this equalisation is no doubt brought about by the escape of products of combustion produced by the engines. When the conducting body is brought down suddenly to earth again, there may be a great difference of potential between it and the objects on the earth. If it is a good conductor, a spark may pass, and if it is, as in the case of a Zeppelin, a conducting body containing a highly inflammable gas, leakage of which cannot altogether be prevented, this spark may cause an explosion and destruction of the airship. Again, the violent electric oscillations created in all metal objects near powerful radiotelegraphic apparatus may cause sparks to jump between metal parts, and hence may inflame a hydrogen leak.

It has therefore been recognised that there are special electrical difficulties in connection with the

working of wireless on rigid airships with metal frames and also in connection with the use of spark apparatus. However carefully the actual working spark is enclosed there is always risk of induced sparks.

There is room yet, therefore, for much research and experimenting in connection with the use of wireless telegraphy on aeroplanes and airships, and the practical problems are by no means completely solved.

This leads to the consideration of the methods we have adopted for dealing with these and all other suggestions of the same kind of the nature of war inventions.

The Royal Society appointed certain committees at an early stage in the war to deal with engineering or mechanical and with chemical inventions. These committees were constituted secret committees, and none of the Fellows, except the council and the small number of the appointed Fellows, were allowed even to know the names of the members. The ostensible reason for this unusual secrecy was that the committees should not be inundated with correspondence from eager inventors and that their work was confidential; but this argument is scarcely valid, because the names of the members of other inventions committees, such as those afterwards appointed by the Admiralty and the Ministry of Munitions, were made public. The publication of the names of members in no way necessitates the publication of information as to their work. In the formation of such committees the important qualification should be not merely scientific or theoretical learning, but sufficient practical knowledge of the matters considered.

The men whose opinions are valuable on war inventions are the men who have to use them, namely, experienced military and naval officers. Again, the value of an invention can usually only be estimated by a practical trial, and this means expenditure. It is an almost impossible matter to judge of an invention merely from a written description. An idea may be old or a method may be familiar, and yet it may be carried out in detail in such a manner as to have great practical value under certain conditions. The ability to form a correct judgment of an engineering invention requires a very wide experience, since it is not easy to appreciate the good points or anticipate the defects of an invention or suggestion or idea which has not been put to the test of practice. Nevertheless, the experts appointed by the Ministry of Munitions are doing valuable work in sifting out the useful ideas from the hundreds already submitted to them.

It is beyond any doubt that this war is a war of engineers and chemists quite as much as of soldiers.

The 42-cm. Krupp gun which smashed in a few days the fortifications of Liége, Namur, and Antwerp, which were confidently expected to hold out for months, is only a piece of heavy engineering. The complete gun weighs 87 tons, and the foundations or carriage 37 tons. Two hundred men are necessary to erect and work each gun, which requires twelve railway waggons for its transport and is composed of 172 parts. It takes twenty-five to twenty-six hours to erect in place. The projectile or shell weighs 8 cwt., and is 5 ft. 4 in. long and 16½ in. diameter. It is fired electrically from a distance of about a quarter of a mile, and each shot costs £550. The range at which the Liége forts were destroyed was fourteen miles. The mere transport and erection of this gun, let alone its manufacture, demands engineering knowledge of a special kind. It is the same with smaller arms. The rifle, except as a support for a bayonet, has almost become obsolete in face of the machine-gun.

To win this war we have to achieve engineering feats. The mammoth howitzer, the great armoured triple-engined aeroplane, and the quick-firing machine-guns are all products of the engineer's workshop, and the pivot round which all Germany's maleficent power turns is Krupp's works at Essen, and the chemical and ammunition factories in Westphalia. The knock out blow will be given at those points, and they must be reached through the air if trench work proves too slow.

But in addition to the concentration of engineering knowledge and skill on the problems of the war, we have to think as well of what will come after. What is required is not merely opinions on inventions already made, but the proper organisation of inventive power and scientific research to bring about new and useful results. This is only to be achieved by bringing to bear adequate combined inventive or scientific power on definite problems which are not too far removed from practical possibilities.

We have as yet made scarcely any progress in the creation of a disciplined army of scientific workers which shall embrace all the abilities in the Empire. We are still in the stage which by comparison with an army is that of a mob of civilians equipped for war with shot guns and sticks.

One reason for this, I think, is because our chief scientific body, the Royal Society, has not taken upon itself more the function of guiding and assisting the general direction of research and invention.

The real function of the Royal Society should be to organise, direct, influence, assist, and promote scientific research, and to do it by an efficient organisation embracing the whole of its Fellows. It represents, or should represent, the very best ability in all departments of scientific knowledge, and it should be organised into grand committees of subjects, as suggested by Professor Armstrong, on one or more of which every Fellow should have his place. The work of these grand committees should be to guide and instigate research in their own departments, to organise general discussions on leading questions in the manner undertaken of late years by the British Association, and to help to direct towards common and important ends the powers of scientific investigation in our universities and colleges.

The special and technical societies provide the facilities required for the reading of papers. A paper on physics, chemistry, or engineering as a rule receives better discussion and criticism if read at the Physical, Chemical, or Engineering Societies than at the Royal Society, and the discussion on a paper, if proper time and notice are given, is often quite as valuable as the paper itself. Although the individualistic method of research in which each scientific worker takes up whatever kind of research he pleases has produced good results in the past and is in agreement with our national characteristics, it is a serious question whether we shall not have to put limits to it in the future. The problems which await solution require in many cases combined or co operative research. One of the most useful improvements in the proceedings of our learned societies would be the devotion of more time to well-organised and predetermined subjects of debate with the object of advancing knowledge at the boundaries of cognate sciences.

This applies to the purely scientific problems, as well as to the problems of industrial research. It must be remembered that, after this war is over in a military sense, we shall immediately commence another war of a different kind, in which the weapons will not be bullets and shells, but our national powers of invention, scientific research, commercial organisation, manufacturing capabilities, and education, and these will be pitted against those of a highly organised Germany determined to win back in commerce by any and every means, fair or foul, that which has been lost in war.

That commercial and industrial war will be waged by our enemies with the same ruthlessness and neglect of all scruples as their military operations. We have said good-bye now and for ever to those easy-going amateur British methods which have held us in the past. What we require is to obtain a higher percentage efficiency in all our operations. We have to attain larger and better results in education, scientific research, and industrial work to increase our national output in every way.

We have been buying dyes, chemicals, optical instruments, and drugs from Germany, glass from Austria, arc-light carbons, electric machinery, and a hundred other things we have no need to buy, and the reason is that we have been shirking the effort and research necessary to make them as cheaply or as well at home. But the England with a national debt of 2,000 to 3,000 millions sterling will be a different kind of place to live in from the England of the year before last, and we shall have to adapt ourselves to the new conditions by new methods of work.

One of the most important of these, I venture to think, is the extension of co-operative research, both scientific and industrial. In the case of industrial work manufacturers are afraid of making their wants and difficulties known, lest the mere statement of them should enable a British rival to find a solution and get ahead. It is necessary to appreciate, however, that rivalry between British manufacturers is not nearly such a serious matter as the competition of Germany with all of them will become, and that British manufacturers will have to stand shoulder to shoulder to meet the common foe. German firms do not hesitate to pool their knowledge if it enables Germany to get ahead of other nations, and British trades will therefore have to meet this organisation by one of a similar kind. In the same manner I have long been convinced that far greater advances might be made in purely scientific research in many departments of knowledge if we were to adopt more extensively the custom of associated work. I mean by this the formation of committees of workers, not too large for expeditious decisions, but charged with the duty of investigating certain formulated problems. It is in this respect that our learned societies might do so much more than they do. The proceedings of these societies are mostly a record of isolated, disconnected pieces of work of very different scientific value. But if properly organised discussion were brought to bear on the question, it would be possible to induce investigators of reputation and ability to associate themselves more in conjoint work to the great advantage of our common knowledge. The learned societies should therefore fulfil to the adult and experienced investigator the same function which the professor or teacher should fulfil to his research students, viz., supply them with suggestions for lines of research to stimulate thought and invention.

It is quite certain that we shall have to organise in this way to a far higher degree than we have yet done what may be called the strategy of research, and that the learned societies should act in some capacity like the great general staff of an army towards the subordinate generals and corps commanders. We require therefore to get on to the councils of our learned and technical societies, and into their presidential chairs, not merely men eminent for their private researches, but men of large ideas with organising abilities and inspirational power. If we do not do this, then, although by a lavish sacrifice of life and treasure we may win, as we are determined to do, in the military and naval operations, we shall in the long run be hopelessly defeated in that slower but none the less deadly scientific and commercial competition which will follow upon the cessation of actual hostilities.

OPENING SOUTH CHINA COAL FIELDS.

There is a very fair prospect for the development of some of the coal fields of South China, especially within Hong-Kong's trade territory, on a modern basis. At several localities along the West and North Rivers near Canton coal fields have been worked in native fashion for some time, and the output has come to amount to a considerable

volume. A mining expert, reports the United States Consul-General at Hong-Kong, has had occasion to look into one of these fields in the past few weeks, with a view to development along modern lines, and gives some facts of interest. The property examined is situated on the North River, about 160 miles from Canton, the actual mine being located about a mile from the river on the right bank. The survey for the Canton Hankow railway lines crosses the property. The property occupies broken ground, embracing two lines of hills of considerable height. The native workings are located from 800 to 1,000 ft. up the side of one of these ranges, and the seam has been followed down for about 400 ft. The seam ranges about 9 ft. in thickness.

The native method of working is extremely wasteful, and also extremely dangerous, even where the seam is so plainly exposed as it is in the case of the one worked. On this property there are three seams, one about 9 ft. in thickness, the second about 2 ft. in thickness, and the third about 10 ft. in thickness. While, owing to the broken nature of the country, it is impossible to see whether or not there are faults in the seams, the general indications are that there are none.

The region is essentially coal country, the predominating rock is limestone intermixed with layers of sandstone and slates. Millions of tons of coal are actually in sight. The Government analyst in Hong-Kong reports on the analysis of a sample of this coal that 100 parts contain 0·80 per cent. of moisture, 17·60 per cent. of ash, 20·70 per cent. of volatile combustible matter, and 60·90 per cent. of fixed carbon. The percentage of sulphur is placed at 1·2 per cent., and the calorific value is 12,830 British thermal units. The ash is greyish white in colour. The coke is of hard behaviour when burned, and burns with a fairly long flame.

The matter of transportation has been one of the chief factors in opening such mines. The North River, where these coal seams are found, is too shallow for successful water transportation and there is no economical means of transport at this time. It is anticipated, however, that the Canton Hankow railway line will be completed to this district in about two years at the present rate of progress—that is, it can be completed to that point in that time out of the earnings of the portions of the road already completed and in operation. The completion of this line will not only immediately open up this coal field, but it will also make other fields available for the Hong-Kong coal market and for export.

The immediate need of these fields at present is modern machinery and capital for development. The capital needed for the development of the property examined is placed at about $150,000 gold, and apparently this may be taken as representative of various other fields. On the basis of this investment an output of 500 tons of coal per day is indicated.

SPITZBERGEN IN 1914.*

Spitzbergen remains a No Man's Land despite the many acquisitions of land by subjects of more than one nation. Insecurity of tenure and considerable lawlessness are the result of this lack of control, and the economic development of the country is hindered. Among the minerals which occur in Spitzbergen are large quantities of coal, magnetite, and gypsum. Valuable marble is also found. Almost all the mineral-bearing territories on the west have been claimed by different companies, chiefly British: the east is less accessible, but several British claims occur there also. Altogether British subjects claim about 7,000 square miles of territory, on which several mines and quarries have been opened. Americans have the most valuable coal mines, exporting annually large quantites to the north of Norway. It is tertiary coal, but of excellent steam quality. Russian enterprise in Spitzbergen ceased over fifty years ago, when Russian trappers stopped frequenting the land. Lately there have been some small attempts on the part of Russians to acquire mining claims. Swedish activity has always been chiefly centred in exploration, particularly of a geological nature. Norway has a few unimportant mining claims, and a few years ago erected a powerful wireless installation. German claims were never of importance.

Hunting fur-bearing animals is a dying activity, due to the approaching extermination of the game by ruthless hunters. On the west game is now very scarce.

The proximity of Spitzbergen to the British Isles and the mainland of Europe is generally overlooked, owing to the use of Mercator maps. From Norway it is only 400 miles, and it is within fifty hours' steaming by a fast cruiser from our shores. The west coast is remarkably free from ice, even in midwinter, and the winter climate does not preclude the continuance of mining throughout the year. In winter a number of miners are at work on British and American mines.

BRACKEN AS LITTER.†

In view of the present high cost of feeding stuffs, it is necessary that as much as possible of their manurial value should be recovered in the dung. The fact that the ordinary supplies of potash are meanwhile cut off furnishes another reason for preserving manure, especially liquid manure, with great care; liquid manure is rich in potash. In districts, therefore, where straw is scarce, or where it can be profitably fed to stock, farmers and horse-keepers should use for litter any other suitable material that may be available at a reasonable cost. Bracken or "fern" is specially worthy of attention at the present time.

* Abstract of a paper read by R. N. Rudmose Brown, D.Sc., before the Geographical Section of the British Association in Manchester.

† Special leaflet issued by the Board of Agriculture and Fisheries.

"Bracken" possesses considerable value as litter, and in many places it may be obtained for the cost of cutting and carting. Bracken harvested while still green usually contains as much phosphoric acid as straw, and much more nitrogen, but less potash. If exposed to rain throughout the winter a considerable loss of substance is likely to result, although bracken cut in April has been found, on analysis, to have a similar composition to straw.

Bracken possesses a considerable power of absorbing ammonia and urine. To secure the full absorptive effect, however, bracken must be very thoroughly trampled upon by stock.

Dung made from bracken may be expected to be equal in chemical composition to dung made from straw. On the other hand, it takes longer to decompose in the soil, the fibrous woody stem being only slowly attacked. It therefore opens up the soil more, and is for that reason likely to be more useful on a heavy clay than on a light sandy soil. Bracken should be cut and dried in autumn, but where this is impracticable it may be cut and carted during suitable weather throughout the winter months.

ARTS AND CRAFTS.

Stained Glass.—The Medici Gallery is better adapted than most London exhibition buildings for the display of stained glass, as it faces on the open street at right angles to Grafton Street and so gets a good supply of direct light. Now, after two exhibitions of Mr. Louis Davis's glass, it has been housing a little show of the work of several artists, men and women. The point which struck one most forcibly at first sight is one which all those who are contemplating the erection of a stained-glass window will do well to bear in mind—the excellence of the stained glass was almost invariably in inverse ratio to that of the sketches. That this is often the case has, of course, been recognised by experts from time immemorial, but it has not always been realised by the general public—it would, indeed, have been rather strange if it had been. At the Medici Gallery the fact was plain for all the world to see. The visitor looked at the sketches and cartoons, and thought one or two of them rather ugly and others full of promise, and on turning to the glass itself found that his judgment was generally reversed. The reason for this is not far to seek. The artist who conceives his glass as glass with the light shining through it is at a disadvantage when he tries to represent his ideas on paper, whilst the man or woman who thinks first of the design and then sets out to translate it into glass naturally makes a much better job of his drawing, especially if it be a small sketch. Another interesting feature of interest was the number of women exhibitors. Women have for some years now been turning their attention to stained glass design, but this is the first time that the work of so many of them has been shown in London at the same exhibition. In this case the most important glass was shown by a lady worker. Miss Esplin's lights of the Three Wise Men, designed for the clerestory windows in the south transept of Khartoum Cathedral, were the most remarkable and the largest windows on view. They showed a very serious purpose as well as a thorough understanding of the material. The glass is very rich in colour, and on a gloomy autumn day in London it looked rather heavy and sombre, but the quality which makes it difficult to judge in England at this time of year ought to stand it in excellent stead in Africa. It is easy to imagine the window lit up by a tropical sun, as a mass of gorgeous and dazzling colour appropriate both to the portrayal of the Eastern kings and sages and to a southern country. The design of the figures is simple and dignified, and sufficiently un-Western to make the work fit for its position. Amongst the other exhibits, Miss M. A. Rope's two-light window of the Crucifixion was well worth notice, and some of Mr. Reginald Hallward's work was interesting. Mr. George Kruger's designs for domestic windows were distinctive, and Miss Townsend's clever little skit in glass, entitled Fabians at the Forge, and representing Mr. George Bernard Shaw and Mr. Sidney Webb hammering (or attempting to hammer) the world into shape, is the kind of joke that will bear preserving in stained glass. At a time like the present, when many people, unhappily, are considering the advisability of putting up memorial windows, it is a real boon to be able to see the actual work which artists have carried out, and not to be obliged to choose a designer from hearsay or from the usually unsatisfactory evidence of his sketches.

The Design and Industries Association.—The Design and Industries Association has begun in good time to justify its existence by the organisation, in conjunction with certain representatives of the Whitechapel Art Gallery, of an Exhibition of Design and Workmanship in Printing at the gallery in the Whitechapel Road. The association has now a considerable membership, drawn from the ranks of artists, craftsmen, art-masters, distributors, and well-wishers. It is noticeable that since its inception the number of distributors and others who are not artists has considerably increased, and its first exhibition should mark an epoch in its career. It shows, at any rate, the sincerity of the desire on the part of the members to get into touch with trade conditions and to influence industrial production on a large scale, rather than handicraft pure and simple. Mr. Morley Fletcher's speech at the inaugural meeting held earlier in the year raised the hope that the society really had this aim in view, not merely theoretically, but in a broad and practical way, and suggested that some of its members had seen fit to change, or, at any rate, to modify pretty considerably, the opinions which they had formerly held. The exhibition now open leaves no doubt of the committee's intentions. A few examples of finely printed old and modern books, which appeal

(so far as purchasing is concerned) only to the wealthy, are, indeed, shown, but the great majority of the exhibits consists of posters, show-cards, advertisements, wrappers, and such-like things connected with ordinary trade printing. The general effect of the exhibition is admirable, and it made one wonder more than ever why a certain section of the public had been so enamoured of the German and Austrian exhibits collected at the Goldsmiths' Hall. However much the Germans may have excelled in certain lines (the case of books from the Central School of Arts and Crafts contains certainly one book with very attractive German paper sides) their output as a whole, at any rate as represented in England, cannot be said to excel ours, and the present exhibition goes far towards proving it. It covers nearly the whole range of general commercial printing, and should appeal every whit as much to the advertiser and the purely trade printer as to the artist and that larger public more or less interested in art.

Printing at the Whitechapel Art Gallery.—The exhibits at Whitechapel are, of course, mainly British, but it was a pleasure to find amongst them a few well-known posters by Grasset, Chéret, and Toulouse de Lautrec. The copies of Boutet de Monvel's children's books revived many pleasant memories, whilst the cheap topical woodcuts dealing with the war, and in a very different style the fashion illustrations, were well worth looking at The Polish and Russian postcards and illustrated books, too, included some remarkable pieces of colouring.

The posters are naturally the most striking feature of the collection, and they are of peculiar interest because, in the recent Printing Trades exhibitions, this class of work has not been very thoroughly represented. Therefore, although those connected with design and advertisement realised the enormous strides made in poster production within recent years, and though the change in the ideals pursued must have been apparent to all who scanned the hoardings with any attention, there has been little opportunity of seeing the best examples side by side. Here are to be found works by Tony Sarg, Fred Taylor, Norman Keene, Dudley Hardy, William Nicholson, J. Hassall, A. S. Hartrick, George Kruger, and other well-known poster designers. They advertise a great variety of things, but those designed for the Underground form a peculiarly satisfactory group. The Prospect of the River, by Joseph Pennell, Chiswick Mall, by F. Ernest Jackson, and the striking lithograph posters by Frank Brangwyn, suggest that lithography might be used much more effectively than is generally the case over here for poster work. Because thirty years ago bad lithographic work was the fashion, we are not bound to conclude that lithographic posters must inevitably be unsatisfactory. There are only one or two letterpress posters, but they are of such a nature as to show how effective good lettering by itself can be.

The group of gaily and attractively coloured biscuit boxes showed another very practical way in which art may come to the aid of commerce. The cases containing books printed in good type, and border designs and illustrations schemed to form a homogeneous whole with the letterpress, represented adequately the highest type of book production, whilst examples of satisfactory colour-work for book illustrations were not wanting. The publishers' announcements make clear to those who do not already know it, how much the form of advertisements of this type has improved in the last few years. The series of publishers' dust-covers demonstrates the opportunities which design for this kind of work offers to the designer.

At once the most novel and the most satisfactory feature of the exhibition, however, is the courage of its promoters. They have not merely been content to exhibit anything and everything on which they could lay their hands, but they have chosen the objects which in their view illustrate what they have to say, and, whilst confining themselves for the most part to exhibits which they consider commendable, they have not hesitated to include a few instances of bad or inartistic workmanship to show how much less effective it is than equally simple work arranged with some reference to the claims of art. Thus amongst a collection of business lists and catalogues are inserted examples of a good and a bad furniture catalogue placed conveniently close to one another, so that no one can avoid seeing the difference between them and drawing the moral. Certain other exhibits are boldly catalogued as well-designed, and a copy of the harmless but rather poor design which has for years been used for the cover of the National Competition report is exhibited side by side with a suggestion, quite as plain and much more successful, which comes from a provincial school of art. It must be confessed, however, that the problem for the art school has been somewhat simplified by the fact that the designer has not been hampered by being forced to include the official version of the royal G. R. with its accompaniment of the crown, rose, shamrock, and thistle. So many people who go to exhibitions are in need of some sort of guidance to enable them to understand what they are looking at and to grasp why certain objects are put before them, that these few attempts to explain why some of the exhibits are in their places ought to be of very great assistance.

NOTES ON BOOKS.

THE SPIRIT OF THE SOIL. By G. D. Knox. London: Constable & Co., Ltd. 2*s*. 6*d*. net.

Some eighteen months ago Professor W. B. Bottomley read a paper before the Society in which he described various experiments undertaken by him to test the value as a fertiliser of bacterised peat. The paper attracted considerable notice at the time among agricultural and horticultural circles.

Since then Professor Bottomley has been continuing his work, and he read a further paper on the subject at the last meeting of the British Association, which was hailed by several speakers in the subsequent discussion as holding out promises of no little importance.

Briefly, Professor Bottomley's treatment is this. Peat, which has been sterilised by steam, is treated with a mixture of nixtrogen-fixing organisms—*Azotobacter chroococcum* and *Bacillus radicicola*—and after these have been incubated for a few days at 26° C., the peat is ready for use. The bacteria at once proceed to fix nitrogen, and the fertility of the soil is increased.

At a time when the food resources of the Empire, and of these islands in particular, are becoming a subject for more and more anxious thought, it is needless to emphasise the importance of anything that may tend to increase the output of our own lands; and it would also seem that the time is opportune—now that the experts have agreed that Professor Bottomley's methods are to be taken seriously—for a popular explanation of the whole matter. This is the object of Mr. Knox's book. After a preliminary discussion of the nitrate problem and our food supply, he gives a simple account of bacteria and protozoa, and the methods of fixing nitrogen adopted by leguminous plants. From this he passes to bacterised peat, vitamines, and elementary conceptions of chemistry in relation to the soil, and finally to the testing and preparation of humogen, as the bacterised peat is called. Although a popular writer, Mr. Knox has had a sound scientific training, and in spite of its somewhat poetical title, this volume may be relied upon as "an accurate exposition of a new development in agriculture and horticulture, which may have an important bearing on the national food supply."

AN EXPERIMENT IN INDUSTRIAL RESEARCH. Educational Pamphlet No. 30 issued by the Board of Education. By Thomas Lloyd Humberstone. London. H.M. Stationery Office; Wyman & Sons, Ltd. 4*d.*

The experiment described in this pamphlet was devised by the late Professor Robert Kennedy Duncan, of Pittsburgh, and a Fellow of the Royal Society of Arts. Some account of it was published in the *Journal* of September 1st, 1911, in an article entitled "Commerce and the Universities," reprinted from the *Times*; but at a moment like the present, when so much attention is being directed towards the perfection of German methods in organising the relations between research, finance, and manufacture, it may not be out of place to give some further consideration to Professor Duncan's remarkable scheme, which has for its principal object the co-ordination of these three interests.

Like many other people, Dr. Duncan held an opinion anything but favourable of "research" as it was generally carried on in the factories. Chemists were—unfortunately, one can still say are—engaged at miserable salaries, and because no prospects were held out, only inferior men would look at the offers. "95 per cent. of the so-called factory research is worse than loss," said Dr. Duncan, "because the failure makes it impossible for the factory to appreciate the advantage of applied science"

Dr. Duncan then set himself to devise a way whereby well-trained chemists of good academic standing might be attracted to industrial work, and as a result he worked out the scheme of Industrial Fellowships which came into operation in the University of Kansas in 1907, and in Pittsburgh University some three years later. The scheme is thus described by Mr. Humberstone: "A contract is entered into between the manufacturer and the University in which the object of the research is precisely defined. The contract provides that the Fellow selected to conduct the investigation desired shall devote his whole time to the research, with the exception of three hours a week, which he may devote to instructional work in the chemical department. The Fellow is a member of the University . . . and works under the direction of the professor of industrial chemistry, and forwards to the manufacturer periodically, through the professor, reports on the progress of the work. The manufacturer agrees to pay to the University an annual sum for the emoluments of the Fellow during the term of the Fellowship." Clauses in the contract provide for the Fellow's share of profits arising from discoveries, and for the publication of results for the use and benefit of the public.

Mr. Humberstone discusses the conditions of the Fellowship from the point of view of (1) the University; (2) the manufacturer; (3) the Fellow; and (4) the public.

The University gains by the presence of a body of highly-qualified men—many of the Fellows have taken their doctor's degree—enthusiastic as to the value of research and the opportunities for it offered by applied science. The manufacturer has placed at his disposal all the resources of a great institution, with well-equipped laboratories, museums, libraries, etc. He is entirely free from the responsibility of selecting the man best qualified to investigate his problems, and his financial outlay is precisely defined. The Fellow is brought into direct touch with the manufacturer: he works in ideal surroundings, with opportunities of consulting his colleagues who may be engaged upon kindred problems; and his training provides a good chance of securing permanent employment at an adequate salary and with a recognised status. The advantages to the public are obvious, as anything tending to the increased efficiency of industrial organisation must eventually tend to the benefit of the nation.

In the University of Pittsburgh forty-four Industrial Fellowships have been established. They deal with a great variety of subjects, and have already led to a good many practical and valuable results. The emoluments vary considerably—in

some cases they run from £100 to £200 a year; in others the Fellowships are composite, a number of men being engaged on the same problem. Thus, *e.g.*, an exhaustive research is being conducted on the smoke nuisance; a large staff of investigators has been organised, and a sum varying from £2,400 to £3,000 a year has been devoted to the investigation.

Enough has been said, it is hoped, to show that Dr. Duncan's scheme is bold and original. The Board of Education deserve our thanks for printing Mr. Humberstone's lucid account of it, and one trusts that by this means the scheme may be brought to the notice of educational authorities and manufacturers in this country.

THE BRITISH COAL-TAR INDUSTRY. Edited by Walter M. Gardner, M.Sc., F.I.C., Principal of the Bradford Technical College. London: Williams & Norgate. 10*s.* 6*d.* net.

Since the outbreak of the war a great deal of attention has been directed to the manufacture of synthetic dyestuffs, and this not so much on account of its magnitude—the annual value of the dyes used in Britain was not much over £2,000,000—as because our dependence on Germany for these materials threatened our textile trade and other industries, the annual value of which was something like £220,000,000. As a result of this publicity, the story of the coal-tar industry—how it originated with Perkin's fortuitous discovery of the mauve dye, and how it passed into German hands in spite of the fact that most of the raw materials had to be imported from Britain—has become, one might almost say, common knowledge. But although the general outlines are so familiar, the details are exceedingly intricate and the whole matter is of the greatest interest and importance. The success of the Germans in the dyestuffs industry has led to endless ramifications in corresponding directions, *e.g.*, the production of synthetic medicines, photographic drugs and fine chemicals generally, artificial fertilisers, and what is, perhaps, at this moment the most important of all, the manufacture of high explosives on an enormous scale.

In these circumstances it is hardly necessary to insist that it is the duty of those responsible for the future of British industry to make a careful study of the causes which had led to the success of the Germans in these particular lines, and Mr. Gardner's object in compiling this volume has been to present the materials for such a study in a readily accessible form. The book contains the principal lectures and addresses given in this country on the subject since the establishment of the industry by Perkin in 1856 down to the present day. It begins, appropriately enough, with Perkin's Cantor Lectures on "The Aniline or Coal-Tar Colours," which were delivered before the Society in 1868, and it may be interesting to Fellows to note that of all the lectures, etc., reprinted in this volume over one-third have been given in the Society's Great Room.

The result of Mr. Gardner's work is an extremely valuable compilation, which seems to include the *omne scibile* of the coal-tar industry. Incidentally he himself, in an article reprinted from *Nature*, gives, in a very few words, an account of the German dye industry, which explains the secret of its success:—

"The German colour industry is probably the most complicated, most highly developed, and most profitable of all her great industries. The capital invested in it is about £12,000,000, and the German exports of dyes and associated products in 1912 were valued at £10,000,000. The organisation, both for production and for marketing and distribution, is wonderfully efficient, and, above all, the Germans have long realised that in this branch of industry the scientific mind and scientific method must be predominant, not only in the laboratory and in the works, but in the management. The boards of directors of their large works are virtually committees of technical and commercial experts, who are in intimate touch with the respective branches of the works of which they have special knowledge. In a word, the trained man of science has in these works come to his own, and a proper recognition of the necessity of this is vital to the development of the British colour industry."

GENERAL NOTES.

SWINEY LECTURES ON GEOLOGY.—A course of twelve lectures on "Ice and the Ice Age" will be delivered by J. D. Falconer, M.A., D.Sc., F.G.S., F.R.S.E., F.R.G.S., in the lecture theatre of the Victoria and Albert Museum, by permission of the Board of Education. The lectures will be given on Mondays, Tuesdays, and Saturdays, at 3 p.m., beginning Saturday, November 13th, and ending Tuesday, December 7th.

FOREIGN SOAP IN CHINA.—According to the American Consul-General in Hong-Kong, there have already been some notable results as to the substitution of Japanese and other cheap soaps for German and Austrian soaps, formerly forming a great part of the trade. While, of course, certain well-known brands of soap of European manufacture enjoy a prestige in Hong-Kong and its trade territory, which are the natural results of years of trading and advertising, the China soap trade as a whole is a matter of comparative price and quality. Up to two years ago Great Britain had the great bulk of the trade, and she still enjoys the larger share. However, she had lost trade proportionately, while Japan had gained even before the war in Europe interfered with the manufacture and export of soap from that part of the world. With the advent of war the stock of foreign soap was greatly reduced, giving Japanese and Hong-Kong manufacturers a notable advantage; but later there was interference with imports of soda ash from Great Britain, and for a

time it looked as though there would be serious interference with the manufacture of soap in this part of the world. There is more or less difficulty in securing such supplies at present, but apparently those difficulties are less than those experienced by European makers in securing certain other supplies they usually import from other portions of the world.

Road Surfaces in the Federated Malay States.—The Director of Public Works Department, Federated Malay States, reports as follows regarding the bituminous treatment of road surfaces: Extensive trials have been made in Perak, Selangor, and Negri Sembilan with the use of bituminous substances for binding and sealing the upper crusts of road surfaces. In Perak the experiments were confined to Kinta, where 45,900 square yards of tar macadam and 55,000 square yards by the penetration method were laid. The cost seems to be from two to two and a half times the cost of similar water-bound surfacing, and there appears to be evidence that the life will be more than two and a half times that under the old method. It is too soon to form a definite opinion. In Selangor hardly any tar macadam has been tried, but tarco has been used very extensively. A sum of $86,000 was spent on 18½ miles of road tarcoed for the first time, and 30½ miles of road tarcoed for the second time. Where the traffic is not too heavy, and the road foundation is good, tarco seems successful, but until it is known how long the use of tarco delays the necessity of remetalling, it is impossible to compare costs. In the meantime, careful records of costs are being kept, not only where tar macadam or tarco is being used, but on adjacent portions of ordinary water-bound road, so that in time a definite comparison can be made.

A Vanilla Plant.—A vanilla-producing plant, *Vanilla ovalis*, has been found on the island of Mindoro (Philippines). The plant has roots similar to those of amlong, and found to be superior to amlong for use in basketry, as they are pure white and require no bleaching. The plant also has a leaf similar to that of one kind of amlong (*Pothos rumphii*), and in growth the two plants are very similar. The leaf of the vanilla plant, however, differs somewhat from the leaf of amlong in that it is unusually thick and is sessile. The plant is found both in open ravines and in deep forests, but is not plentiful. The Bureau of Education is investigating the plant with a view to ascertaining whether it may be developed commercially in making vanilla extract for trade purposes.

Seeth Manure.—Seeth, which consists of the residues of the indigo plant after the indican has been extracted, is well known as a valuable manure for tobacco. Its usefulness depends mainly on its power of aerating the soil and giving the tobacco roots an ample supply of air. Experiments are at present being conducted at the Agricultural Research Institute, Pusa, with the object of securing better returns from seeth. Evidence has been obtained that if the tobacco lands are mixed with small pieces of tile the amount of organic matter for the crop can be reduced. The cost is not very great, and a plot which was improved at Pusa in this way nine years ago still shows its superiority. If the present supply of seeth can be made to produce the same results on two or three times the area, the factories will be materially assisted and the indigo industry will receive an indirect benefit.

Argentine Tobacco Output.—According to *La Prensa* (Buenos Aires), the manufacture of cigarettes in Argentina last year reached a total of 550,000,000 boxes, while 300,000,000 cigars and 9,920,700 lbs. of leaf tobacco were produced.

THE LIBRARY.

The following books have been presented to the Library since the last announcement. Except where otherwise stated they have been presented by the publishers:—

Amphlett, George T.—History of the Standard Bank of South Africa, 1862-1913. Glasgow: Robert Maclehose & Co., Ltd.

Balls, W. Lawrence, M.A.—The Development and Properties of Raw Cotton. London: A. & C. Black, Ltd., 1915.

Beaumont, Roberts, M.Sc.—Woollen and Worsted. London: G. Bell & Sons, Ltd., 1915.

Berry, Henry F., I.S.O., Litt.D.—A History of the Royal Dublin Society. London: Longmans, Green & Co., 1915.

Birdwood, Sir George, K.C.I.E., C.S.I., LL.D., M.D.—Sva. Edited by F. H. Brown. London: Lee Warner, 1915. Presented by the Author.

Bone, Philip J.—The Guitar and Mandolin: Biographies of Players of these Instruments. London: Schott & Co., 1914. Presented by the Author.

Brenchley, Winifred E., D.Sc.—Inorganic Plant Poisons and Stimulants. Cambridge University Press, 1914. Presented by the Director, Rothamsted Experimental Station.

Calvert, Albert F., F.C.S.—Salt in Cheshire. London: E. & F. N. Spon, 1915.

Carpenter, Charles, D.Sc.—The Purification of Gas by Heat. London: South Metropolitan Gas Co., 1914. Presented by the Author.

Cleveland-Stevens, Edward, M.A.—English Railways. London: George Routledge & Sons, Ltd., 1915. Presented by the Director of the London School of Economics.

Cox, J. Charles, LL.D., F.S.A.—The English Parish Church. London: B. T. Batsford, Ltd., 1914.

Cressy, Edward.—Discoveries and Inventions of the Twentieth Century. London: George Routledge & Sons, 1914.

Crew, Albert.—Procedure at Meetings. Third Edition. London: Jordan & Sons, Ltd., 1915.

Darling, Charles R.—Liquid Drops and Globules. London: E. & F. N. Spon, Ltd., 1914.

De Villamil, Lieut.-Colonel R.—Motion of Liquids. London. E. & F. N. Spon, Ltd., 1914.

Eliot, Charles W.—The Road toward Peace. Boston. Houghton Mifflin Co., 1915. Presented by Dr. S. T. Armstrong.

Ficke, Arthur Davison.—Chats on Japanese Prints. London: T. Fisher Unwin, Ltd., 1915.

Franzen, Dr. Hartwig.—Exercises in Gas Analysis. Translated from the German by Thomas Callan, Ph.D. London: Blackie & Son, Ltd.

Gage, Professor Simon Henry, and Henry Phelps Gage, Ph.D.—Optic Projection. Ithaca, New York: Comstock Publishing Co., 1914.

Gardner, Walter M., M.Sc., F.I.C.—The British Coal-Tar Industry. London: Williams & Norgate, 1915.

Gaster, Leon, and J. S. Dow.—Modern Illuminants and Illuminating Engineering. London: Whittaker & Co., 1915.

Hardy, G. Hurlstone.—The Book of the Fly. London: William Heinemann, 1915. Presented by the Author.

Hobhouse, L. T., G. C. Wheeler, and M. Ginsburg.—The Material Culture and Social Institutions of the Simple Peoples. London: Chapman & Hall, Ltd., 1915. Presented by the Director of the London School of Economics.

Holloway, Thomas.—Levelling and its General Application. Third Edition. London: E. & F. N. Spon, Ltd., 1914.

Indian Year Book, 1915. London: Bennett, Coleman & Co., Ltd., 1915.

Kirkpatrick, Frederick A.—Imperial Defence and Trade. London. Royal Colonial Institute, 1914.

Knox, Gordon D.—The Spirit of the Soil. London: Constable & Co., Ltd., 1915.

Lawson, H. Heaton.—English and Commercial Correspondence. London: Blackie & Son, Ltd., 1914.

Leong, Y. K., LL.B., B.Sc., and L. K. Tao, B.Sc.—Village and Town Life in China. London: George Allen & Unwin, Ltd. Presented by the Director of the London School of Economics.

Martin, Edward A., F.G.S.—Dew-Ponds. London: T. Werner Laurie, Ltd.

Motor Cyclist's Handbook, by "Phœnix." Fourth Edition. London: Percival Marshall & Co., 1915.

Oakenfull, J. C.—Brazil, 1913. Frome: Butler & Tanner, 1914.

Peddie, J. Taylor.—(1) First Principles of Production. London: Longmans, Green & Co., 1915; (2) On the Relation of Imports to Exports. London: Longmans, Green & Co., 1915.

Pennell, Joseph, and E. Robins Pennell.—Lithography and Lithographers. London: T. Fisher Unwin, 1915.

Perris, George Herbert.—The Industrial History of Modern England. London: Kegan Paul, Trench, Trübner & Co., Ltd., 1914.

Phillips' Paper Trade Directory of the World, 1914-15. London: S. C. Phillips & Co., 1915.

Plimmer, R. H. A.—Practical Organic and Bio-Chemistry. London: Longmans, Green & Co., 1915.

Pulbrook, Ernest C.—The English Countryside. London: B. T. Batsford, Ltd., 1915.

Richardson, S. S., B.Sc.—Magnetism and Electricity. New Edition. London: Blackie & Son, Ltd., 1914.

Russell, Edward J., D.Sc.—(1) Soil Conditions and Plant Growth. New Edition. London: Longmans, Green & Co., 1915; (2) The Fertility of the Soil. Cambridge University Press, 1915. Presented by the Author.

Scott-Mitchell, Frederick.—Practical Gilding, Bronzing, etc. London: The Trade Papers Publishing Co., Ltd., 1915.

Scudder, Heyward, B.A., M.D.—The Electrica Conductivity and Ionization Constants of Organic Compounds. London: Constable & Co., Ltd., 1914.

Skrimshire, Samuel, F.S.I.—Valuations. London E. & F. N. Spon, Ltd., 1915.

Stratton, Mary.—Bruges: a Record and an Impression. Illustrated by Charles Wade. London B. T. Batsford, Ltd., 1914.

Talbot, H. H.—Blackie's Modern Business Arithmetic. London: Blackie & Son, Ltd., 1914.

Todd, John A., B.L.—The World's Cotton Crops. London: A. & C. Black, Ltd., 1915.

Travis, Charles.—Railway Rates and Traffic. Translated from the third edition of C. Colson's "Transports et Tarifs." London: G. Bell & Sons, Ltd., 1914.

Twelvetrees, W. Noble.—Rivington's Notes on Building Construction. Two Vols. New Edition. London: Longmans, Green & Co., 1915.

Verrells, H. Victor.—Experimental Hygiene. London: Blackie & Son, Ltd., 1912.

Vizetelly, Frank H., Litt.D., LL.D.—(1) The Development of the Dictionary of the English Language; (2) Essentials of English Speech and Literature. New York: Funk & Wagnalls Co., 1915. Presented by the Author.

Wilder, Gerrit P.—Fruits of the Hawaiian Islands. Honolulu: Hawaiian Gazette Co., Ltd., 1911. Presented by the Author.

Wireless Time Signals.—London: E. & F. N. Spon, Ltd., 1915.

Wolf, A., M.A., D.Litt.—The Philosophy of Nietzsche. London: Constable & Co., 1915. Presented by the Director of the London School of Economics.

Year Book of Wireless Telegraphy and Telephony, 1915. London: The Wireless Press, Ltd., 1915.

Journal of the Royal Society of Arts.

No. 3,284. VOL. LXIII.

FRIDAY, OCTOBER 29, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CANTOR LECTURES.

The Cantor Lectures on "Foodstuffs," by David Sommerville, B.A., M.Sc., M.D., Assistant Professor of Hygiene and Public Health, King's College, London, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures, which have been published separately and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

HOUSE BUILDING: PAST AND PRESENT.*

By M. H. Baillie Scott.

Lecture I.—Delivered March 15th, 1915.

The subject for this series of lectures is a very wide one. I hardly realised how wide it was till I began to write about it, and I soon found that the main problem before me was not what I could say about it, but what I should be obliged to omit. After much consideration, I have deliberately chosen to deal mainly with what I may call, for want of a better word, the artistic aspect of building. In so doing I do not wish you to suppose for a moment that practical efficiency is not of fundamental importance. It is, in truth, the only sound foundation for worthy artistic ideals. But I think the modern tendency is to confine our attention too exclusively to the material aspects of the problems involved in building, and to consider the art of the matter as an entirely separate consideration, and not as the leaven which should humanise and spiritualise the whole of the enterprise. Because we rightly believe that sanitation is important, there is no reason why we should always be groping in the drains, forgetting the heavens above us. It is well that every material comfort and convenience should find its place in the modern house, but, since man cannot live by bread alone, the house should minister to something more than material needs, and should indicate some of those aspirations of the spirit which we find expressed in the old houses. The main object I have in view, then, is to indicate some of the obstacles to the realisation of this ideal, and to consider how they may be removed.

Before considering house building in the past or the present, it seems desirable to get some clear conception in our minds as to what building really means to us, and in what the art of it consists.

I believe I am right in assuming that the general modern impression about building is that in its simpler forms it is a rather dull sort of trade, and that only when it becomes elaborate and complicated does it become worthy of regard as an art. This elaborate building is popularly recognised as architecture It is built from the designs of architects, and may be readily distinguished from ordinary building because it has certain well-recognised architectural features. It has columns copied or adapted from Greek or Roman temples according to the fashion of the day, or in buildings set apart for religious purposes it may have Gothic pinnacles and cuspings. Now all these technical matters are little understood by the people, and even the highly educated are often timid in their judgments in matters connected with building. The architects are the high priests of the mysteries of architecture, and whatever they choose to do is accepted with equal

* All the houses illustrated are designed by the author.

FIG. 1.—"BURTON HOUSE," NEAR SHERBORNE. (The Entrance Front.)

indifference and apathy by the public. Of recent years, in public buildings, the architecture based on the ponderous gloom of Roman buildings has been all the mode, and this manner is carried on concurrently with various other fashions in smaller buildings. And, meanwhile, ordinary plain building is neither studied nor understood as an art. It has never apparently occurred to anyone that ordinary plain building is an art. The attitude towards building and architecture, which has led to this merely because it possesses unnecessary features and ornaments. A building is not to be transformed into a piece of architecture by mere trimmings, any more than a plain man is to be made into a gentleman by adopting a conventional garb. Let us clear our minds from all the recognised cant about buildings, and look at the realities of the situation; and, in order to get a more wholesome conception as to the qualities of building, let us compare the building art, which is so little understood and so seldom

Fig. 3.- "Burton House," near Sherborne. (The Hall.)

state of affairs in the building world, is supported by many high authorities. On referring to "The Seven Lamps of Architecture," by John Ruskin, I find it assumed, as a matter of course, that building itself is unworthy of regard as art, and it only becomes architecture when it includes useless features. He says architecture concerns itself only with those characters of an edifice which are above and beyond its common use.

Now I wish at the outset to dispute entirely this modern conception of building and architecture, and I refuse to reverence any building studied, with another art which is better understood and is more fully recognised—I mean the art of literature.

In choosing and arranging words on a page the purpose of the writer is essentially a practical one. It is his aim to convey a certain meaning by a certain arrangement of words, and we measure his power by the skill shown in such arrangement, which in its highest developments becomes what we call literature. Now it is quite impossible to say at what particular point mere writing becomes literature. It certainly does not

become so by the addition of unnecessary words or by elaboration of any kind. Indeed, on the contrary, I believe I am right in saying, and I believe that the best judges of literature will agree, that the test of good work is that its statements are direct and simple, and that no word can be removed from them without injury to the meaning. All this is well understood, and in such great works as the Bible, for instance, we find quite simple and artless tales which we all recognise as fine examples of this particular art. Now the principles which underlie all arts are the same, and so in the art of building, considered in its broadest aspect, we shall find man engaged, not in arranging words on a page, but in arranging brick and stone and wood on the earth. Here again the purpose of his work is fundamentally practical, and it becomes architecture, as writing becomes literature, not by elaboration or by ornament, or by any unnecessary trimmings, but by the skill and insight disclosed in the use of the means at his disposal. In building, as in writing, the real qualities of the work are elemental and not accessory. They cannot be extricated from fundamental construction. It is impossible to make any distinct dividing line between building and architecture. The best figure which I can put forward to illustrate my conception of building is to think of it as a plant we are growing which, if our gardening is good, may break into flower. The flower is the reward of the right kind of root culture. It may be quite unexpected and undreamt of. And this living bloom is quite a different thing from the imitation flowers deliberately copied from the classic gardens. It is evolved naturally and inevitably from the very life of the plant, and cannot be stuck on from outside. Here again it will doubtless be recognised that this figure of the plant represents the situation as regards writing and literature, for it is doubtful whether the best of the world's writers knew or cared whether they were producing literature. They merely used the best words to convey their meaning, and the beauty of their work was a thing they were unconscious of. But in the case of building we have no critics who understand it as literature is understood, and while the latest novel or musical comedy is the subject of expert criticism in the press, buildings are seldom considered as works of art at all. And as in modern times we have become a nation of newspaper readers, and as we consciously or unconsciously take so much of our opinions from newspapers, a great opportunity is lost of educating the public taste in matters connected with building by the lack of recognition of the building art in the popular press. A new church is vaguely referred to as in the Early English style of architecture, and the writer is obviously unaware that Early English architecture was the expression of the soul of Early England, and that the reproduction of the same forms in modern cast-iron workmanship, according to contract, is but an empty husk compared with the genuine article it imitates. For there is all the difference in the world between an inspired creation and the imitation of an inspired creation.

In trying to show that the merit of a building does not necessarily lie in the architectural features, I do not wish to suggest that all elaborate building is to be condemned, but merely that beauty in building does not necessarily consist in elaboration, and that generally a certain simplicity will be the mark of the best work. Elaboration and ornament seem to me only justifiable as the spontaneous expression of the joy of the worker—a breaking forth into song. As such it stands in the building as a kind of petrified joy, and persists as a symbol of something great indeed. But, since the corruption of the best is always the worst, when elaboration and ornament is used in a perfunctory and lifeless way, it becomes a useless stupidity In building, as I understand it, while we are bound to do honest and sound work, we are in no way bound to use elaborate ornament or architectural features, and there is no mysterious alchemy which transmutes plain building into architecture by such additions.

It does not come within the scope of my subject to deal with public buildings, and I only allude to them in passing, because they illustrate some curious developments in building methods which so far have not yet shown themselves in house building. The fashion of the day for public buildings may be expressed in the following formula. Work out your structure in a skeleton of steel and concrete, and when this is done conceal these essential factors of the constructional scheme with a screen composed of architectural features copied out of books. The curious compound resulting from this fundamentally unsound and dishonest process is usually described as classic architecture. But those of us who have our own conception of classic architecture may perhaps be pardoned for not accepting it as such. Picture to yourselves for a moment the Greek temple: think of the broad spaces of sunlit marble, the brilliant

colour of its sculptures, and the exquisite subtleties of its outline, and then turn from this bright and beautiful vision to the dismal gloom of the buildings we now claim to be classic in their inspiration. One is reminded of a certain scene in the "Diary of a Nobody," when an imitation of Irving was proposed by a visitor to a suburban household. Whereupon the hostess, a lady more remarkable for domestic virtue than personal charms, entering gleefully into the business in hand, said, "And I'll be Ellen Terry." Just as gleefully and irresponsibly does the modern architect set forth to be Greek. It is easier to be Roman perhaps, for that is the heavy-father part. The departed spirit of Bumbledom must be invoked, or perhaps Malvolio. You must be gloomy and impressive. It is called the "Grand Manner." Above all, you must not laugh. One imagines that just one explosion of mirth would shatter and destroy all these solemn nightmares. Classic architecture in the modern world—and the Grand Manner of building generally—stand for pride. There is no humility in it, and the antic man postures and plumes himself at large. And the cure for all this is the proper cultivation of a sense of humour. It is much to the credit of modern life that these bombastic buildings do not interest anyone, and the only reason for their production is due to the fact that all public buildings are produced under a competitive system, in which the professors of the Grand Manner are at present the sole arbiters.

FIG. 4. "BURTON HOUSE," NEAR SHERBORNE. (The Hall Fireplace.)

In the building of houses there is some small hope of better things, because those who still understand something of the possibilities of building as an art may find in the house a means of expressing their ideals, untrammelled by official standards. But the trend of modern thought is so largely infected by utilitarian and mechanical ideas that the general atmosphere is too often fatal to the growth of any real building art. The house is considered as merely a combination of conveniences, hot-water taps, labour-saving appliances, and so on. I have no

wish to undervalue these things. They are undoubtedly of great importance. But I can never accept a hot-water tap in exchange for all those noble qualities which have been and may yet be expressed in building, and I would rather think of the house as a temple to the household gods than as a mechanical contrivance which would reduce all human activities to the single act of pressing a button. I think it was Professor Lethaby who said, "A house should be as efficient as a bicycle." That is quite true as far as it goes. But it is apt to mislead us if we suppose that the problems involved in building a house or in making a bicycle are of the same kind. The function of the bicycle is such that in making it all our doings are strictly governed by insistent conditions which admit little latitude for creative choice, and its ultimate form is the resultant of remorseless material forces. But in the building of a house no such conditions restrict us. We have to enclose and to roof over a piece of space, and subdivide this space for the purposes of habitation, and according to the usual modern formula we may allot spaces for drawing-room, dining-room, and so on. Now I do not think you can tell me of any natural law which insists on any definite size or shape for any of these apartments; and, supposing the house to be wind and weather proof, to be conveniently arranged and completely warmed and lighted, there is still a large margin for creative choice in its forms and details—in the proportion of its rooms, in the technique of its workmanship, and in the qualities of its materials. It is, then, impossible to escape from the conclusion that the

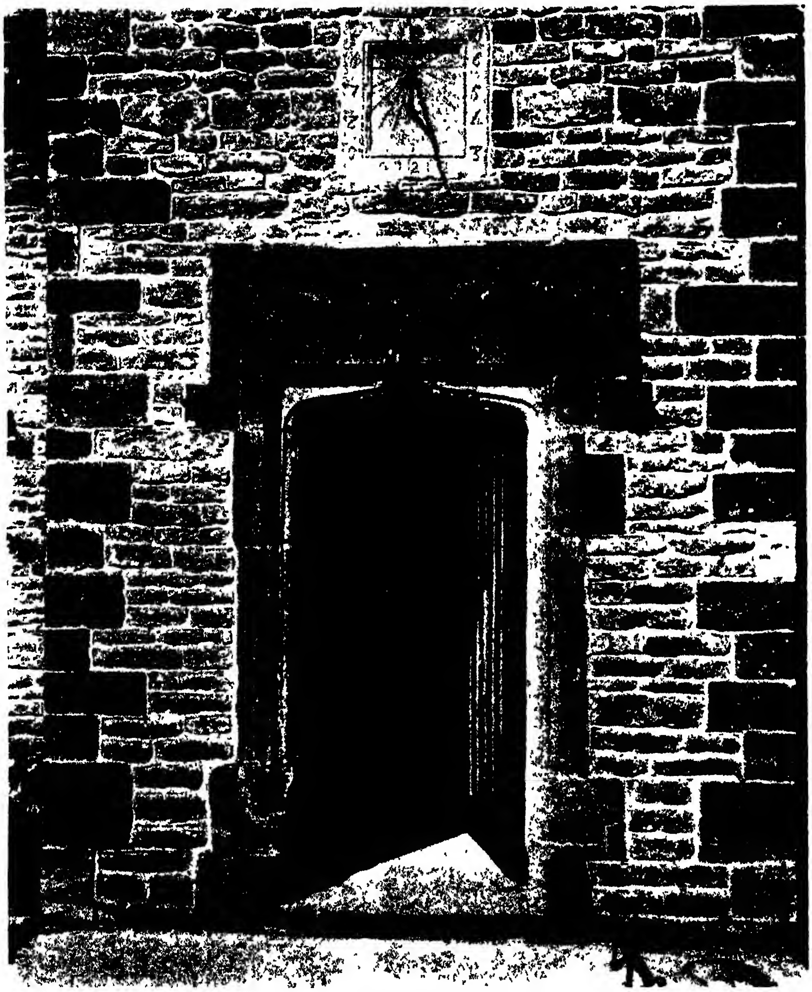

FIG. 5.—"BURTON HOUSE," NEAR SHERBORNE. (Garden Porch.)

creation of a house is essentially an artistic matter involving deliberate selections and rejections, not entirely subject to utilitarian restrictions; art, either good or bad, cannot be excluded from its conception and execution. And the most valuable kind of art in house-building is that which is intimately associated with the proportion of its masses and the very bones of its anatomy, so that, when stripped of all its superficial adornments, its wallpapers and its curtains, it still preserves unimpaired, if unadorned, its essential qualities.

the modern bicycle is better than the old bone-shakers or velocipedes, as they used to be called in the days when cycling was a fearful and hazardous adventure. But there is this difference between the proper subjects for scientific study and those which are governed by artistic principles. In the former we may expect advance and improvement coincident with the material progress of civilisation, but in the latter it is often found the earlier work is better than the later, and so the old picture may often be better than the latest expression in painting,

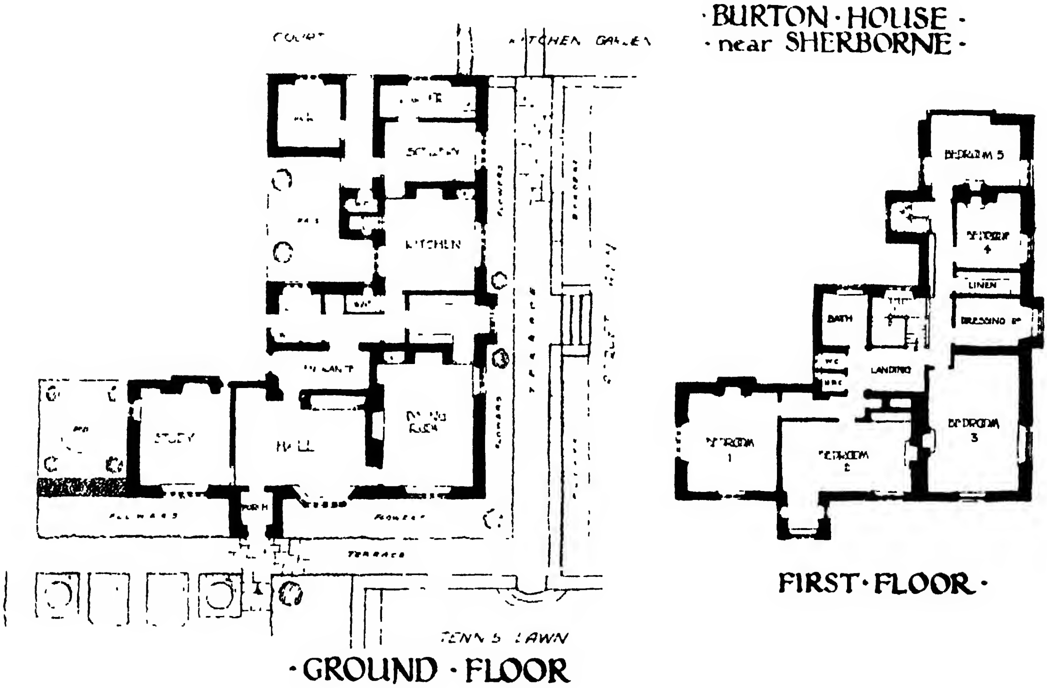

Fig. 6.

The idea that house building is merely a matter of practical utility and not, like the painting of pictures for instance, essentially an art, leads us naturally to suppose that the modern house is necessarily, as the outcome of a long experience, especially adapted to our needs, and in every way an advance on the older houses. If we wish to obtain the greatest efficiency in a locomotive, we should not in these days be inclined to use the earlier types of engines, and we rightly prefer a Rolls-Royce motor-car to Stephenson's "Rocket," for the whole development of such means of locomotion has been a continual advance in efficiency. So

and the old house better than the modern villa. Give me an old house—let it be as early in date as the twelfth century if you like—and after adding a bath and cooking range, and a few hot-water pipes, which constitute almost the only contribution to the efficiency to the house that modern times have supplied, the old house shall make as good a dwelling for all practical purposes as any modern house, and in addition, as a work of art, it has a value difficult to measure or describe in words and qualities, which with all our enlightenment and knowledge we have forgotten how to produce.

In thinking of building, then, I want to try

to dispel the idea that architecture is an elaborate and complicated kind of building which we in our modern enlightenment have evolved out of the darkness and ignorance of the past. I want to substitute for this conception of the building art the idea that whatever real greatness a building may possess is rooted in the essential facts of its structure. It lies in little homely everyday things and in work affectionately done.

This old way of building we have lost, and, until we can regain it, it is idle to indulge in extravagant dreams about architecture, for all true architecture grows out of good building. It cannot exist without a universal habit of good building. And do not let us imagine that art is in any way degraded or obstructed by the fact that it has to deal with practical problems such as are involved in ordinary building. Pure art, as it has been called, which lives in a dream world apart from the actualities of our daily life, soon becomes emasculated and trivial. Lacking the tonic influences which contact with life brings, it loses its virility and ends by becoming a frivolous and dilettante affair, practised by a limited cult of superior persons. If we consider the works of Nature, we shall find no pure art there. The most beautiful creations all have their practical functions to perform. There is no part of the trees or flowers which is not designed for a purpose to which it is delicately adjusted, and in the human frame the beauty of eye would be nothing without sight, the arm nothing without might. Beauty in all these cases cannot be extricated from its connection with practical functions. If art is to have any real significance it must cling closely to life, and be the informing spirit in all man's doings in the world, and its central task must be concerned with the creation of houses with all the appointments of daily life.

The idea that there is something vulgar in usefulness, and that art is only to be concerned with useless tasks, is a doctrine which flourished in Victorian days. It is a doctrine which is dying hard to-day. It is a doctrine which is refuted by every old English town and village and by all the treasures of our museums, while the fruits of it are seen in the manifold ugliness of modern life. Let us hope that art may be again what it has been in the past, the reward of all constructive labour, and not only the possession of a few, so that the craftsman may recapture some of that dignity and joy of life which was once his portion and his heritage.

TOBACCO, GINSENG, AND COTTON CULTIVATION IN KOREA.

Tobacco.

The annual importation of yellow tobacco leaves from America by Korean manufacturers as material for the manufacture of cigarettes, amounts to about 828,000 lb. In view of this the Government-General has for several years been carrying on experimental plantations of American tobacco in Korea. It has shown that the climate and soil of that country are well suited for the cultivation of this species. In 1912 the Government-General established a station in Choongju, North Choongchongdo, for experimental work, and at the same time for the encouragement of tobacco cultivation among the local farmers. According to a report by the United States Consul-General at Seoul, the result was satisfactory, the area of land devoted to this variety of tobacco being steadily on the increase. In the first year (1912) the ground planted with it was only thirty-seven acres, but last year it increased to 294 acres, with a crop weighing 331,200 lb. As the cultivation is carried on only under the direction of the experiment station, cultivators are required to secure permission of the authorities before planting (in January or February). Since tobacco leaves produced on one acre of ground range in value from £8 to £16, the yield is quite lucrative to the farmers. Under the circumstances many farmers are now desirous of undertaking its cultivation; but, fearing over-production, the authorities believe it advisable to restrict the area. It is reported that 1,225 acres is the area for which permission has been requested for 1915, but that the aggregate area destined to receive official permission is only 490 acres.

Ginseng.

Ginseng farms harvested in 1914 aggregated 161,906 kan (about 647,624 square yards), producing 280,166 lb., of which the Government purchased 75,969 lb. of the best grades at a cost of £35,000, or 9*s*. 3*d*. per lb., for the manufacture of red ginseng. In comparison with the average annual production of the six years ended 1913, there is shown an increase of 33,675 lb. as the result of the strict measures taken by the Government for the prevention of disease, which has heretofore hampered this industry. The roots harvested in 1914 were planted in 1909.

Cotton.

The total area of land devoted to the cultivation of cotton of the Upland species during 1914 was about 51,450 acres, the crop obtained being estimated at 28,000,000 lb. in weight. As a result of the encouragement given to farmers to plant this grade of cotton, the area devoted to the industry is increasing year by year, and it is estimated that during 1915 land planted with Upland cotton will reach 83,300 acres, an increase of 31,850 acres over the preceding year.

MILITARY TRAINING IN SCHOOLS.

As a sign of the times it is interesting to note that no fewer than three papers on the subject of military training in schools were read before the Education Section of the British Association at Manchester.

Mr. A. B. Wood presented a review of the systems of training in the British Empire, and in various foreign countries, with the object of supplying some undisputed facts as a basis for the scientific discussion of the problems. In the brief printed abstract of his paper one or two cases only are given.

Australia.—In Australia all male inhabitants (except those specially exempted) are liable to military service in time of peace as well as in time of war. This principle of compulsory military training was made law in 1909, and came into operation in January 1911. The Defence Act provided compulsory military education for boys as follows:—

Rank.	Age.	Service.	Training.
Junior Cadets	12-14 years	2 years	Annually—90 hours.
Senior Cadets	14-18 years	4 years	Annually—4 whole days, 12 half-days, and 24 night drills.
Citizen Forces (Militia)	18-26 years	8 years	Annually—In first 7 years drills equivalent to 16 whole days (including 8 "camps").

When in full operation this system involves the training of 100,000 Senior Cadets and 128,000 Militia (the population of Australia—excluding aboriginal natives—being about 4½ millions). The Junior Cadets (12-14) are given a general physical training, including swimming, first-aid, and miniature rifle-shooting. Senior Cadets (14-18) are subject to military discipline, and have regular military drills and rifle practice. On attaining the age of 18 the boys, if fit, are transferred to the Militia.

The expense of this training, as part of the educational system, is wholly included in the ordinary Education Budget.

Certain provision is made for "religious objectors" and "anti-militarists."

Reports by the Premiers of the various States of the Commonwealth give ample testimony to the success of the system.

New Zealand.—By the Defence Act of 1910-11, compulsory military training is provided for every male person between the ages of 14 and 35 years. Between the ages of 12 and 14 the boy receives a certain amount of physical training in the elementary school. At 14 he joins the Senior Cadet Corps, his subsequent training being now conducted on lines similar to the Australian system.

South Africa.—The Defence Act of 1912 provides that all boys between the ages of 13 and 17 years shall undergo a prescribed course of military training annually. The Act provides for compulsory military training "only where it can be carried out efficiently," *i.e.*, in urban and populous areas. In scattered districts Defence Rifle Associations are formed.

Sweden.—Compulsory military training was introduced into Swedish schools fifty years ago. Military exercises are given in all secondary schools, special emphasis being placed on rifle practice, at which 60 hours annually must be spent by every boy between the ages of 15 and 18 years inclusive. In elementary schools physical exercises are given regularly, but no rifle practice.

Norway.—The system here is similar to that of Sweden.

The value of this military training is estimated by referring to the reports of the respective Governments. All these reports describe the compulsory system of training as a great success, both from the point of view of the boy as an individual and the nation as a whole.

In the British "system," which is entirely voluntary, much excellent work is done by various voluntary organisations, such as Church Lads' Brigades, Miniature Rifle Clubs, School Cadet Corps, Boy Scouts, etc., and it becomes necessary to decide whether or not such a voluntary system could be improved by adopting a more centralised and systematic Government organisation of Cadet Corps on lines, say similar to that of the Australian system.

The second paper, by the Rev. A. A. David, discussed the subject from several points of view:—

1. *Its Bearing on National Needs.*—The question is not altogether separable from the wider question of Universal or National Training. It is fair to point out that the recent sudden demand for a very large number of officers in all branches of the British Army would not have been met as it has been but for the careful and continually improving military practice in public schools for the last thirty years, but especially since 1908.

2. *Suggestions for a Continuous Course.*—At elementary or preparatory school stages—drill and scouting. In public schools—ditto, with field practice and elementary tactics and much exercise in handling squads, sections, etc., leading

to Certificate A, and at a later stage to further training for officers and Certificate B.

3. *Effects on the Individual Boy.*—(a) *In body.* Good drill demands and induces alertness of ear, ready attention, and muscles under instant control. Physical exercises for straightening, smartening, and strengthening, are probably best done as part of military training. And all this is most easily taught and learnt quite early in school life. (b) *In capacity and character.* To prepare a man to be a soldier means to produce in him faculties and powers which are of more than merely military value, *e.g.*, in connection with the giving, receiving and transmitting of orders, the appreciation and enjoyment of smartness and orderliness, and later on responsibility, initiative, and leadership. (c) *In intelligence.* Experience has proved the educational value for older cadets of tactical problems for Certificate A, map-making and reading, and other field work.

4. *Effect on the School.*- Here again experience has shown that a good training corps reacts on the life of the whole school. For instance, in boarding schools it is now exerting and, it is hoped, will continue to provide a wholesome check upon the undue exaltation of games; whereas in day schools, where compulsory games are often impossible, it supplies a wholesome and practical form of exercise and change of interest. And it has also been found that a really efficient corps raises the standard of discipline, and even of efficiency in other departments of school life. But the drill must be good. Bad drill is worse than no drill. Much of the opposition to school training dates from a time when little was expected of Volunteers, before they were taken seriously by the authorities.

5. *Objections.* – The objectors fall into two classes: (*a*) Those whose hatred of all war leads them to condemn all military training whatsoever. Such views cannot fail to win respect for those who hold them. In a world of hard realities and second-bests we cannot afford to be without men who will thus continually remind us of what ought to be possible, but neither can we afford to act on their advice. (*b*) Those who fear an "English militarism." But why should we suppose that English boys would catch a spirit and follow an example which the whole world is recognising to be ridiculous, odious, and disastrous?

Mr. A. A. Somerville traced the growth of the idea through its various stages, ridicule, recognition, and, finally, gratitude, and dealt with the objections to the movements, and with its effects on individual character, as a centre of discipline and usefulness in the school, its value as a means of training officers, and generally as an example to the country. The present generation, he urged, is undisciplined; the next will have a far higher sense of discipline and duty.

MOTOR FISHING-BOATS IN SCOTLAND.

It is interesting to learn from the annual report of the Scottish Fishery Board that, in spite of the war conditions which have seriously interfered with the fishing industry, not only by severely restricting the areas in which fishing can be carried on, but also by withdrawing large numbers of men and boats for mine-sweeping and other operations, the returns regarding motor fishing-boats again show a substantial increase in the number of registrations, the total for 1914 being 694, as compared with 523 in 1913, an increase of 171. This rise is the greatest that has yet been recorded for any one year. The increase in the largest class (over 45 ft. keel) is one of the striking features of the year.

As in 1913, most of the boats in which motor-power was installed were sailing-boats already on the register, and only a few boats were specially built for motors.

The types of engine which have in past years been found most suitable by the fishermen continued in favour during 1914, although one or two new makes were introduced. In the Clyde and some other districts the tendency towards higher powered motors, which was mentioned in the report for 1913, was again apparent.

The reports received from the Board's officers continue to show that, as a general rule, the cost of installing motor-power is a sound investment. In most cases in which the earnings of motor-boats do not considerably exceed those of sailing-boats of the same size, it appears that the failure was largely due to lack of enterprise on the part of fishermen, and the continued substantial increase in the motor fleet is, of itself, conclusive evidence of the value of motor propulsion in fishing-boats.

PRODUCTION OF YERBA MATÉ (PARAGUAYAN TEA).

The Paraguayan Government has recently compiled figures showing the estimated production of yerba maté (Paraguayan tea) for 1915, compared with the actual production in 1914, from which it appears that there is expected to be a decrease this year. The figures are as follows:—

District.	1914 lb.	1915 lb.
Concepcion	2,843,934	1,979,731
San Pedro	7,987,817	7,028,265
Guaira	--	16,534
Yhu	601,856	1,313,942
Caazapa	22,046	440,920
Encarnacion	5,877,464	4,761,936
	17,333,117	15,541,328

According to a report by the United States Consul at Asuncion, yerba maté is the daily household beverage of the masses of Paraguay, and is consumed also to a large extent in Brazil and Argentina. It has been introduced into Europe, where its use is increasing.

CORRESPONDENCE.

THE VALUE OF BIRDS TO MAN.

The many calls on my time since I returned to London last month have precluded until now the possibility of my replying to Mr. Frank Cundall's letter in the *Journal* of August 20th, 1915.

It is not at all certain that the importation of infected cattle was the agency by which the tick pest was first introduced into Jamaica. There are ten species of ticks in the island, all of which have a wide distribution. The fact that the Texas-fever tick (*Rhipicephalus annulatus*) is found in North and South America, several of the West Indian Islands, Africa, Europe, Asia, and Oceana, and that it was mentioned by Aristotle, makes it extremely unlikely that it found its way to Jamaica only in recent years. My belief is that it has been long present in the island, and that the agency which first carried it there was the wind. With such atmospheric disturbances as occur in these regions it would be strange if the "grass louse" -the tick in its larval stage—had not been carried to the island. My belief that the tick has been long present in Jamaica is strengthened by the fact that native breeds of cattle enjoy an almost total immunity from the plague, while imported breeds suffer terribly. This immunity, I believe, is to be attributed to former attacks, stretching backwards, through generations, just as zebu cattle are not susceptible to rinderpest, or some black peoples to syphilis. In a word, they are inoculated.

I am aware that it is only in comparatively recent years that the pest has become alarmingly manifest. I am also aware that it is only in Jamaica that ticks have become such a pest, and, furthermore, that their inordinate increase is synchronous with the inordinate decrease of insect-eating birds. Up to a little over forty years ago, the period when the millinery interest began its devastating work, bird-life was extraordinarily abundant in Jamaica. In consequence, grass ticks are not mentioned in the records of that time. The balance of Nature's forces had not been disturbed, and the birds were able to exert a constant check on the undue multiplication of the insect. At first, the plume hunter sought only the plumes of the egret and the skins of the humming-bird. Rapidly his evil work widened its scope, until it included all types of birds which carried marketable feathers. The number of bird skins from Jamaica which poured into Europe and into New York City, when the slaughter was at its height, is truly appalling. It is not easy for me to recall to memory the hundreds of thousands I have seen in England, France, Holland, and Germany, without the feeling of indignation I experienced at the time again rising within me. Whole species have been wiped out of existence, while of those that were most abundant only a pitiful remnant remain. We all know that the mongoose is a great culprit, but to attempt to saddle him with the responsibility of this crime is too absurd for serious consideration.

I know that there is a Birds and Fishes Protection Law in Jamaica, which provides for the protection throughout the year of a large number of insect-eating birds. I know, also, that this law is a sham. The only purpose it has served is to fill the mouth of the gunner with laughter.

To understand how easy it was for the bird, under natural conditions, to keep the tick in check, we must consider the life-cycle and habits of the latter. All the Jamaican ticks undergo a metamorphosis, which consists of four stages. The eggs are laid on the ground, agglomerated in a heap. On hatching from the egg, the larvae, or "grass lice," crawl up the stems of grasses, congregating at the top in enormous numbers. As many as 2,250 larvae have been counted at the top of a single blade of grass. The elevated position is chosen because the single end the larvae have in view is to attach themselves to a passing host as it sweeps through the herbage; and they attach themselves to almost all terrestrial vertebrates, including man. When the larva has secured a host, it satiates itself with blood, falls to the ground, moults, and reaches the third stage—the nymphal. The nymph again climbs to the top of a grass stem or other elevated and exposed position, and again awaits a host. The host secured, it gorges itself with blood, falls to the ground, casts its skin, and undergoes the final change, which gives it sexual organs. The fourth stage has been reached. The adults, both male and female, ascend to the top of a tall blade of grass, or other plant, and for the third time await a passing host. The host having been found, they pair, and then both take a meal of blood. The female becomes enormously distended, falls to the ground, lays her eggs, and dies. This sketch is necessarily slight and incomplete, but it will serve to show that throughout the whole life-cycle the tick, in whatever stage it may be, is an invitation for the bird to come and feed. In Jamaica, seventy-four adult ticks, all females in an engorged condition, have been taken from the stomach of a bird after its early morning meal. Mr. Wortley computes the average number of eggs laid by a female tick to be, approximately, 7,000. The number of ticks, therefore, destroyed in the embryonic stage by this bird at one meal was over half a million. We have but to remember that digestion is exceedingly rapid in birds, and that for the most part birds feed most of the time, to realise that the number of ticks eaten by birds, when there were birds to eat them, must have been beyond human comprehension or computation.

The two following extracts from official reports will give some idea of the dimensions the tick pest in Jamaica has assumed since the insects have been left without check.

The first extract is from the Reports of the Twenty-first Expedition of the Liverpool School of Tropical Medicine, Jamaica, 1908-9: "One of the greatest problems which confronts the pen-keepers of Jamaica is the eradication or control of those

ticks, which, by their vast numbers, have rendered nearly all the grazing districts of the island insufferable to man, and a veritable plague to his domesticated animals. For forty years these pests seem to have been rapidly increasing, and to-day they swarm in incredible numbers, and are a menace to the stock-raising industry of the country."

The second extract is from the Report of the Department of Agriculture for 1913–14, issued by the Colonial Government, and published at the Government Printing Office, Kingston, Jamaica, 1915. "Experience teaches us that there is no such thing as immunity for an imported dairy cow in Jamaica, and we must expect all our imported cows to succumb to tick-fever sooner or later."

Mr. Cundall states that the island of Jamaica is remarkably suitable for the breeding of cattle. This, under existing conditions, it never can be Native stock do not fatten until they are four or five years old, while Jamaica-bred cows give but a very poor yield of milk. There must be an improvement in the breeds before Jamaica can hope to hold her own against foreign production and importation of dairy produce. What is required is earlier maturity and better fattening qualities amongst the butcher's stock, and much larger milk production for dairy purposes. This cannot be arrived at. Any attempt to improve the native breeds by importing superior stock must end in failure, since the imported stock die out.

By washing, dipping, and burning pastures, the pen-holders are attempting, at enormous cost, to do a work that the birds, previous to their destruction, had performed free of charge. Yet wash, and dip, and burn, as they may, the pen-holders are obliged to admit that they are impotent against the enemy. The only remedy is to recall the bird. Unfortunately, local opinion on the subject is absolutely dead. But if the people of Jamaica do not awake from their slumber, if they do not crush the bird-destroyer, their chance of ever freeing themselves from the tick pest is a remote one.

JAMES BUCKLAND.

OBITUARY.

CAPTAIN SIR ANDREW NOBLE, BT., K.C.B., D.Sc., Sc.D., D.C.L., F.R.S.—Sir Andrew Noble died on the 22nd inst. at his residence, Ardkinglas, Argyllshire.

He was born at Gourock in 1831, and after being educated at Edinburgh Academy and the Royal Military Academy, Woolwich, he entered the Royal Artillery in 1849, and attained the rank of captain in 1855. In 1858 he was appointed secretary to the Committee on Rifled Cannon, and in the following year to the Committee on Plates and Guns. In 1859 he also became Assistant-Inspector of Artillery, and was employed in the proof department of the Arsenal at Woolwich. In 1860 he was made an associate member of the Ordnance Select Committee, and a member of the Committee on Explosives, on which body he continued to sit until its dissolution in 1880. In 1860 also, on the invitation of Sir William Armstrong, he entered the firm of Sir W. G. Armstrong, Whitworth & Co., Ltd., of Elswick, at first as a salaried official, but shortly afterwards as a partner, and no doubt the great engineering and scientific reputation of the firm was due in large measure to his remarkable powers of organisation

Sir Andrew Noble's researches into the phenomena attending the firing of a gun were started very soon after he became associated with Sir William Armstrong. In 1862 he conducted the first electroballistic investigations made in this country, and invented the Noble chronoscope for determining the velocity of a projectile in the barrel of a gun. Later on, in conjunction with Sir Frederick Abel, he carried out the long series of experiments on "Fired Gunpowder" which have now become classic in the history of explosives.

He next turned his attention to smokeless powders, and to cordite in particular, and after long and laborious investigations he succeeded in obtaining muzzle-velocities of over 3,000 ft. a second, or double those obtainable thirty years before, together with an energy and capacity for penetration about four times greater than had then been practicable. In a lecture delivered before the Royal Institution in 1907 he stated that in the past fifty years he had investigated "no fewer than eighteen distinct propellants, determining for most of them on an elaborate scale the transformations which occurred when they were fired at very different pressures."

In recognition of his services to science Sir Andrew Noble was elected a Fellow of the Royal Society in 1870, and ten years later he was awarded their Royal medal; he received the honorary degree of D.Sc. from the University of Oxford, and of Sc.D. from the University of Cambridge; he was created a C.B. in 1881, a K C.B. in 1893, and a baronet in 1902. He was also member of a large number of foreign orders, including the Crown of Italy, the Sacred Treasure and Rising Sun of Japan, the Rose of Brazil, and the Order of Charles III. of Spain. He became a member of the Royal Society of Arts in 1882, and in 1909 he received the Society's Albert Medal "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

PROFESSOR VIVIAN BYAM LEWES.—Fellows of the Society will learn with much regret of the death of Professor Vivian B. Lewes, which took place on the 23rd inst. at Mold, Flintshire, from an attack of double pneumonia.

He was born in 1852, and was educated at University College, London. In 1879 he became Assistant to the Professor of Chemistry at the Royal Naval College, Greenwich; and on the retirement of Professor Henry Debus in 1888 he was appointed his successor, a post which he occupied till 1914. He was thus well known to nearly every officer in the British Navy, to whom his lectures on high explosives, etc., were always of the deepest interest. He was also Chief Superintending Gas Examiner to the City of London from 1892 to the time of his death. But it was as a popular lecturer that he was best known to the public, and nowhere was he a greater favourite than at the Royal Society of Arts. It is over twenty-five years since he first appeared in the Great Room, when he delivered a course of Juvenile Lectures on "The Story of a Flame." Later on in the same year (1890) he gave four Popular Lectures on the "Atmosphere," and in the autumn a course of Cantor Lectures on "Gaseous Illuminants." In 1892 he read a paper on "The Spontaneous Combustion of Coal and its Prevention," for which he was awarded the Society's silver medal. This paper was followed by the following lectures and papers: Cantor Lectures on "The Generation of Light from Coal Gas" (1892); a paper on "London Coal Gas and its Enrichments" (1894), for which he received a second medal; Cantor Lectures on "Explosives and their Modern Development" (1894); a paper on "The Commercial Synthesis of Illuminating Hydrocarbons" (1895), for which he received a third medal; Cantor Lectures on "The Use of Gas for Domestic Lighting" (1896); a paper on "Water Gas and its Applications" (1898); Cantor Lectures on "Acetylene" (1898); Cantor Lectures on "The Incandescent Gas Mantle and its Uses" (1900); Cantor Lectures on "The Future of Coal Gas and Allied Illuminants" (1902), Cantor Lectures on "Fire, Fire Risks, and Fire Prevention" (1906); Cantor Lectures on "Fuel and its Future" (1908); Cantor Lectures on "The Carbonisation of Coal" (1911); a paper on "The Testing of Safety Explosives" (1913); Cantor Lectures on "Liquid Fuel" (1913); Fothergill Lectures on "Motor Fuels" (1915); and a course of Special War Lectures on "Modern Munitions of War" (1915).

From this list it will be seen that Professor Lewes was a very extensive contributor to the proceedings of the Society. He made no fewer than sixty appearances on the platform of the Great Room, and in this respect he very easily holds the record. His lectures were invariably well attended, frequently crowded. He was undoubtedly a very attractive lecturer: he spoke with a fluency that astonished strangers, and he never had occasion to use a single note. He was, of course, a speaker of very great practice, for in addition to the work which he did in connection with the Royal Naval College and the Royal Society of Arts, he lectured a great deal for the Gilchrist Educational Trust, and for other bodies.

GENERAL NOTES.

Indian Pamphlets on the War.—With a view to fighting against the campaign of lies, wilfully circulated by German statesmen and professors as to the genesis of the war, Mr. Cassamally Jairazbhoy, Vice-President of the Bombay Branch of the Moslem League, has resolved to print and publish occasional pamphlets in English and the vernaculars at his own cost, and to circulate them broadcast among the Indian people. Two of these, entitled "India and the War" and "The Suicide of Turkey," have been received. The first is an examination of German policy and of India's duty in supporting the cause of civilisation. "When the history of the war comes to be written," says the author, "there will be no more interesting and glorious chapter than the bright page dealing with the despatch of Indian troops for the defence of the Empire, the heroic part played by them in upholding the glory of the Empire, and the loyalty shown by her princes and peoples, who are all animated with the desire to wipe out the common foe. This war is meant to decide if modern civilisation shall be ruled by brute force or by the enlightened will of free peoples. India has furnished the only possible reply, which has found eloquent expression in the great wave of loyalty that has swept from the Himalayas to Cape Comorin, and from Mandalay to Karachi." The pamphlets are written with admirable vigour and reasoned constraint, and the fact that they have already run into several editions should assure the author that they are carrying out the patriotic and loyal purpose for which they were intended.

American Cars and Tyres for England and France.—Commenting on the remarkable increase in the exportation of motor-cars from the United States, owing to the European war, the *Autocar* remarks that the actual figures are surprising. Exceeding by far the purchases of all other countries combined, the United Kingdom stands at the head of the list with a total of 4,036 cars, valued at £1,179,171, during the month of May last, as compared with 663 cars, valued at £111,350, during the corresponding month of last year, while for the eleven months ending May, 1915, the figures were 11,688 cars, valued at £3,347,233, as compared with 6,982 cars, valued at £1,122,770, for the corresponding period ending May, 1914, and 3,593 cars, valued at £547,487, for 1913. France took 521 cars during May, 1915, as compared with 275 in May, 1914; the number of American cars exported to France during the eleven month ended with May for the last three years being 4,472 for 1915, 1,286 for 1914, and 753 for 1913. The exportation of American motor-car tyres to England also shows a remarkable increase, their value for the eleven months ended May last being £457,898, as compared with £262,186 for the corresponding eleven months ended May, 1914, and £196,322 for 1913.

Technical Education in West Africa.—The *Colonial Journal* publishes some particulars of the scheme dealing with a sum of £20,000, with accumulations, bequeathed by Sir Alfred Jones for the promotion of technical education in West Africa. £10,750, with an equivalent sum to be contributed by the Government of Nigeria, will be devoted to the building and maintenance of a technical institute or workshops in that Protectorate, for the purpose of elementary education and practical workshop and mechanical training. £5,375 are to go to the building and maintenance of trade schools in Sierra Leone for instruction in blacksmith's, carpenter's, or other manual work. The remainder of the legacy is to be applied to technical education or mission schools in the Gold Coast, under a scheme to be hereafter settled.

The Oxyacetylene Process and Life-saving.—The *Acetylene Lighting and Welding Journal* records the fact that a new use has been made of the oxyacetylene process in preserving life. It will be remembered that the large Chicago passenger steamer "Eastland" suddenly capsized at her moorings on July 24th, with 2,480 souls on board. A large number of these were imprisoned in the inverted hull. Shortly after the accident two members of the city detective bureau recalled having seen an oxyacetylene operator at work on a building at a short distance from the scene of the disaster. They brought him, with his equipment, back to the boat at top speed. In three minutes he had cut a hole 2 ft. by 2 ft. in the half-inch plate next a porthole, and a moment later three half-drowned victims were drawn through the hole. Oxygen apparatus was used for resuscitation purposes. As every second counted, additional operators were procured, and many victims were rescued. The cutting operators worked steadily from the time of the disaster, 7.40 a.m., on the 24th, to 6 p.m. on the following day.

Trade Conditions in Russia.—A feature characteristic of the Russian market, according to His Majesty's Consul at Batoum, is the smallness of the capital employed in trade. Both commerce and industry, particularly in their more modern branches—*e.g.*, sundry machinery, lathes, motors, etc., are mostly in the hands of people without capital, who are, therefore, able to do business only on credit. Credit is an absolute necessity to the great bulk of persons engaged in trade and industry in Russia. German firms knew this well and developed trade extensively, thanks to the credit given. German manufacturing firms have been known to accept orders for up to £12,000 to £15,000 worth of machinery, and to receive only from £2,000 to £4,000 on account, a sum which in most cases would barely suffice to pay duty on the goods and the expense of erecting the plant. The payment of the balance due on the machinery was spread over a period of from two to three years. The sale of motors on a system of one to two years' credit has become a common rule.

MEETINGS FOR THE ENSUING WEEK.

Monday, November 1...Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. W. A. Haviland, "The Effect of the European War on Agriculture."

Asiatic Society, 22, Albemarle-street, 4 p.m. Pandit Shyam Shankar, "Some Issues Raised on the Chronological Assumptions in the History of Sanskrit Literature."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Opening Address by the President (Mr. E. Newton).

Tuesday, November 2...Sociological Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.15 p.m. Mr. A. J. Toynbee, "The Non-Sovereign State: an International Problem."

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Inaugural Address by the President (Mr. A. Ross).

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m.

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. W. H. Smith, "Satista and other Platinotype Papers."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Mr. H. J. E. Peake, "The First Siege of Troy."

Roentgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. Address by the President (Mr. J. H. Gardiner)

Wednesday, November 3...Chadwick Public Lecture, Royal Society of Medicine, 1, Wimpole-street, W., 5.15 p.m. Dr. R. O. Moon, "Typhus in Serbia." (Lecture III.)

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. W. H. Simmons, "Formic Acid as a Reagent in Essential Oil Analysis." 2. Mr. H. L. Smith, "Note on the Melting-point of Salicylic Acid, and a test for the presence of Para-hydroxybenzoic Acid." 3. Mr. E. Hinks, "The Persistence of Hydrogen Peroxide in Milk."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. A. H. Thompson, "The Will of Master William Doune, Archdeacon of Leicester."

Geological Society, Burlington House, W., 5.30 p.m. Dr. C. W. Andrews, "The Discovery of a Fossil Elephant at Chatham."

Thursday, November 4...Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. A. W. Knapp and R. V. Wadsworth, "Reactions between the higher fatty acids and salts of the lower fatty acids." 2. Mr. W. A. Davis, "The interaction of perchloric acid and potassium sulphate as an example of reversible change." 3. Messrs. G. M. and R. Robinson, "A decomposition of certain orthonitromandelic acids." 4. Mr. A. C. Sircar, "The relation between the chemical constitution and colour of azo compounds." 5. Mr. J. G. M. Dunlop, "3-gem-dimethyl piperidine." 6. Mr. S. U. Pickering, (*a*) "Compounds of iron, manganese, lead, and the metals of Group II", (*b*) "Valency." 7. Mr. J. C. Crocker, "The indirect determination of velocity of hydrolysis by the polarimetric method." 8. Messrs. M. P. Applebey and W. Hughes, "The vapour pressures of some saturated aqueous solutions."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace road, S.W., 6 p.m. Miss C. E. Grant, "The American Child at School."

Automobile Engineers, Institution of, 21, Victoria-street, S.W., 8 p.m. (Graduates' Section.) Mr. T. D. Carpenter, "The Production of War Munitions by Motor-car Manufacturers."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Miss G. Bacon, "Flying Machines in Peace and War."

Journal of the Royal Society of Arts.

No. 3,285. VOL. LXIII.

FRIDAY, NOVEMBER 5, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Sixty-Second Session will be held on Wednesday, November 17th, when an address will be delivered by DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council. The subject of the Address will be "English and German Methods Contrasted." The chair will be taken at 4.30 p.m.

The following arrangements have been made for the meetings before Christmas:-

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:-

NOVEMBER 24.—SIR EDWIN PEARS, "Constantinople, Ancient and Modern."

DECEMBER 1.—THE MASTER OF CHRIST'S COLLEGE, CAMBRIDGE (Arthur Everett Shipley, Sc.D., F.R.S.), "Insects and War." SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., will preside.

DECEMBER 8.—LIEUT.-COLONEL W. A. TILNEY, 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

DECEMBER 15.—J. JEF. DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." (With illustrations.)

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

NOVEMBER 30.—SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica, "Recent Developments in Jamaica: Internal and External." SIR HENRY A. BLAKE, G.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:

DECEMBER 16.—C. C. McLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas:

LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., "Optical Appliances in Warfare."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION

Thursday afternoons at 4.30 p.m.:—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 21, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass and Optical Instruments." Three Lectures.

November 29, December 6, 13.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April, 3, 10.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 o'clock. The lecturer and subject will be announced later on in the *Journal*.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

HOUSE BUILDING: PAST AND PRESENT.*

By M. H. BAILLIE SCOTT.

Lecture II.—Delivered March 22nd, 1915.

In considering the houses of the past in this country, I want to try to pierce deeper than the mere external forms in which building expressed itself from time to time. I do not propose to speak of Early English work, or decorated, or perpendicular, or of tracery and pointed arches. All this morphology of the building periods has been exhaustively dealt with and exactly measured, tabulated and described. It is all extremely interesting, but not of great value unless we can get from the work some conception of the spirit that informed it. The building art is, like other arts, the medium for the expression of the individual or combined group of individuals who produced the work. What they sowed we may reap, no more and no less, and the spiritual appeal of a building represents the sum of the spiritual energy put into it by its builders the heart inspiring and the brain guiding the dexterity of the hand. I give this trinity of factors in the order of their importance. The most vital matter is the inspiration, the divine spark in the work; the brain gives rational guidance, and the hand is the medium of expression. If the true inspiration is there, we may forgive some lack of intelligence in the brain and halting powers in the hand. If some great thought is seeking expression the readiest and simplest language is the best. The knowledge which the brain can acquire and the skill which the hand can attain to are of little worth except as servants to the ideal, and the whole tragedy of the development of any art lies in the pride of knowledge and skill, in mere proficiency for its own sake, which reduces the whole art to the level of an acrobatic performance. If we consider the deeper significance of the art of building in the past, we shall find it divides itself naturally into three periods:-

First, the craftsman period extending from the earliest Gothic times, through the Middle Ages up to the time of the Renaissance.

Second, the scholar period dating from the Renaissance till about the end of the eighteenth century.

Third, the shopkeeper period, when the commercial ideals of the nineteenth century found their expression in building.

These three periods are not clearly defined by the dates referred to. Long after the Renaissance the earlier tradition of the craftsman lent warmth and colour to the work of the scholar period, and led to several curious phases in transitional blends, and after the end of the eighteenth century many curious manifestations of moribund scholarship occur.

There is always something childlike in the best kind of art, and one of the best definitions of art seems to me the one which describes it as the survival in man of the play instinct of the child. In the craftsman period we may

* All the houses illustrated are designed by the author.

FIG. 7.—"UNDERSHAW," GUILDFORD. (Entrance Front.)

FIG. 8.—"UNDERSHAW," GUILDFORD. (View from Garden.)

compare the builders to a happy eager band of children building castles on the seashore. They are working for the best of all motives, to please themselves. And so all goes well with them and their work. And then we may imagine the coming of the Renaissance in the person of some pompous and dignified professor who engages to teach these happy builders how their work ought to be done according to classic precedents. The children, somewhat crestfallen, are not unwilling to try a new game, and continue to extract some amusement for a time with quaint variations on the classic themes, but they gradually realise that the old happy holiday work is over, and lesson time and grammar has begun. But still they continue to find some pleasure in the school work which has been thrust upon them.

Then comes along the shopkeeper, who points out to the professor and his pupils that all this working for fun as the children did at first, or working according to rules set by the professor, is really not what is required at all. It isn't practical, and it doesn't pay. No; they must work for his profit, and nothing else really matters.

And so these children, who were once happy and free, first become scholars and now have become factory hands. Through endless hours of dull labour they do again and again the same tasks. All the romance and magic has faded out of their work, which is devoid of pleasure both to the producer and the beholder.

My conception, then, of the building period of the Middle Ages is just the opposite to that conveyed by the term generally applied to this period, the "Dark Ages." So far from that, the mediæval building period seems to me the daytime of art in building, and this conception does not rely on any delusive written records. It has been said of the historian that it is his privilege to narrate accurately what never occurred. My records are the actual buildings themselves, and my appreciation of these is not due in any degree to historical associations or the glamour of antique things. Good building is to me good building, in whatever century it may be produced; and no mere passage of time will sanctify bad and ignoble work, and will add little to the initial qualities of a building. And, indeed, one is apt to forget how much of the glories of the old buildings has passed away, and I like to think of the old house and the old church when the work in each was fresh from the hand of the workman, when the chancel screen was bright with gilt and colours, and when the house was gay with all its proper appointments, without the taint of modern trade art, which it is almost impossible to exclude nowadays. And if in modern building the methods of the old builders are advocated, it is not because they are the old methods, but because they are the right methods; and although the final result of their application will lead to a resemblance between the modern house built in the old way and the old house itself, that is merely because in both right principles have been followed. This is quite a different thing from servile imitation, or the unintelligent reproduction of characteristic features of the periods which we find displayed in the showrooms of the modern cabinet-maker. The Tudor room, with all the proper appointments of the period, including a suit of armour propped up in the corner and imitation beams in the ceiling, is no proper setting for modern life, and must necessarily appear an affectation to any sensible person. Many of the simpler features of the Tudor house may, indeed, be put into the crucible of the mind and distilled into a new harmony, subject to those necessary restrictions that the realities of modern life impose; but this is a different matter from the ordinary "period" room as it is called, which lacks reality and suggests the museum rather than the home.

If the mediæval building age may be considered as the daytime of the arts, we may continue the figure and think of the breaking up of the craftsman period as a time having the ripe and mellow beauties of the sunset. In the early part of the eighteenth century the last warm afterglow had faded from the sky, and after that nothing was left but the cold greyness of the later Renaissance, eventually succeeded by the darkness of the Victorian era, the true dark age of the building art. Since then, in modern times, we have had various little local dawns, but no new day has yet arrived on any comprehensive scale in the building world.

Of the three periods of building, then, that of the craftsman seems to me incomparably the best. The art of building during the craftsman period was the central and dominant art of the world, a kind of universal language expressing the ideals of the nation as a whole. To the simple, practical minds of the old builders it was sufficiently obvious that the proper function of art was in the creation of a world of buildings. Art was not a thing to be shut away in galleries and museums, but its proper sphere was a much wider one than that. It was no less than the

adornment of the whole world in which we live. Every village and every town was an artistic creation. From the broken and disfigured remains of this work we can form some faint conception of the beauty of the England thus created in the Middle Ages, when every house was in its degree a work of art in harmony with its natural surroundings. Nothing we structure. We find art here engaged in the service of life, and not, as in the modern world, divorced from life. Like the wanderer Maurice Hewlett writes of, who aimed at making England a garden, the artist of the Middle Ages aimed at beautifying the world with building. And I think we must all admit he succeeded well. For the beauty of England

FIG. 9.—"UNDERSHAW," GUILDFORD. (The Hall.)

have done since, nothing we can do now, is to be compared for a moment with the glory of that building art. It was a living force claiming for its expression the organised and combined efforts of a whole community of craftsmen. And it gives us an object lesson as to the true place of art in the world, primarily concerned with building, and interested in the accessory arts of painting and sculpture only so far as they served to clothe and adorn which still survives to us is not only a matter of the hills, the woods and the fields. We should love Sussex less, I think, and not more, if there were no old villages hidden in the folds of the downs, nor would the austere uplands of the Cotswolds delight us so much without their villages of pearly grey; and in every county we find the old buildings of the locality are not only in harmony with Nature, but they seem to accentuate and interpret its dumb appeal.

So intimately blended is the spirit of the old buildings with their natural surroundings that it would seem as if the same power that created the one had also inspired the production of the other, and so we find throughout the length and breadth of the land the old builder with his magic touch has created new beauties everywhere in village and town, in church and manor, in farmhouse and cottage.

The art of building, then, as practised during the time which I have called the craftsman period, not only successfully solved the practical problems of its day on the material plane, but in doing so it also created a world of beauty; and since we have now lost this art it seems useful to inquire into the methods of these old builders which led to such splendid results. I do not suggest that we should copy the outward aspects of these old buildings, or reproduce lifeless replicas of them, but that we should try to discern something of the heart of their mystery.

The virtue of building as an art does not lie in any particular outward forms. Tracery, cuspings, Corinthian columns, all the accumulated architectural lumber of the ages, are quite useless to us in themselves. The only thing that really matters is the spirit which inspires the producers of the buildings. Given a group of craftsmen, working not only for material gain but inspired by some noble ideal, and their work, in spite of themselves almost, will reveal to the discerning eye something of the quality of the spiritual force which created it. And so it is fitting, in considering the work of this craftsman period, we should go behind the forms in which it expressed itself, and try to discern something of the attitude of the workers engaged in it. In those days we shall find the members of each trade were combined in the form of Trades Guilds. These guilds were combinations of craftsmen for the purpose of building, and the most striking fact about them was that the bond which united them was not a money bond. In these brotherhoods of workers there was nothing equivalent to our system of capital and labour—of masters making profits and labourers taking wages. It is true that the material interests of the craftsman were looked after by the guild The livelihood of the members was secured whether they happened to be working or not. They were free then to work not merely to live, but for the honour and glory of their guild. That, and not mere cash payment, was the bond which held them together. Can we wonder then that their work was something radically different to modern building? The value of the knowledge they accumulated and bequeathed to their successors was of a kind which in these days of book learning we can perhaps hardly appreciate. It was instinctive rather than reasoned, and was a thing too subtle to be formulated by any words. The whole outlook of these old guilds was entirely different from any combination of labour in the modern world. If we take, for instance, the Guild of the Carpenters, we shall find that all the wealth produced by carpentry was in the hands of an organised association of carpenters. In such circumstances we may naturally suppose that carpenters would desire, amongst other things, to get some legitimate pleasure as well as profit out of their work. In existing conditions a shareholder in some factory where timber is ruthlessly dealt with by the machine, cares nothing about carpentry from the standpoint of the craftsman. It is a natural result of the system that he should care for nothing but dividends. If he is philanthropic he may go further, and be interested to know that the workers in the factory have good wages and dwellings. But he is perhaps hardly aware that the craft of carpentry, when practised in the old way, is capable of yielding quite another kind of dividend than that in which he is interested. I mean that joy in creative work which was not the least valuable part of the wages of the old craftsman. Until we can get work done again in the old way, and enlist the hearts and heads, as well as the hands, of every workman in our service, it is idle to hope that we shall produce any sort of building or architecture worthy of the name. Men do not gather grapes of thorns, or figs of thistles, and the ugliness of modern building is the inevitable and natural result of the ugliness of the methods that produce it. In a word, while the normal modern house is the confessed symbol of greed of profit, the old one stood for delight in work. And this delight in work was fostered by the guilds, and there was no outside power then to step in and say, "No, you are to work for my profit and not for your own delight."

I hope, then, I have been able to show that the fundamental cause of the beauty of the building in this craftsman period was the freedom of the craftsman to express all that was best in him in his work. He was something more than a cog in a profit-grinding machine. The civilisation to which he belonged had many faults, but it at least gave the workmen such opportunities as they do not enjoy to-day.

Fig. 10.—Cottages at Gidea Park, Romford. (View from Road.)

Fig. 11.—Cottages at Gidea Park, Romford. (View from Garden.)

I have no wish to pose as a reformer, and I have no "Morrison's Pill" to cure the ills of the labour world; but I cannot help wishing that, when we once more turn our minds to the arts of peace, some organisation of labour, modelled on the old Trades Guilds, may be attempted as the first step to secure some real revival of the art of building. In such organisation the architect must take his place, not as an alien superior person, but as one so intimately associated with labour that he can interpret its dreams in terms his fellow-workmen can appreciate and understand.

The main interest of the old guilds was the building of churches, but when they built the houses which were to enshrine their domestic life they did not adopt a different style of building. Church and house were alike in their main characteristics, and in the creation of each the craftsman found, in a world of wonders not yet classified and defined, opportunity to realise in brick and stone the creations of his fertile imagination. In such conditions, and in such an atmosphere, it is not to be wondered at that the building art of the crafstman flowered into beauty. Much of it, fortunately, has survived to the present day, and from the study of these old houses much may be learnt. If we examine sympathetically an old building of the craftsman period, we shall find that the whole of the fabric seems to be saturated with a kind of human warmth of life, and the unconscious art of it does not lie in any cleverness or feats of skill, but in a glowing warmhearted vitality which seems to permeate it. The whole technique of its workmanship differs materially from modern practice, and such merits as it possesses depend to no small extent in the way in which the work is done.

The great principle which seems to have been unconsciously divined by these old builders is that each material used has its peculiar qualities, and in its handling these qualities are to be recognised and developed. Thus, the bricks in the walls are patently made of burnt clay. That is to say, in their surface and outline they have the kind of surface and outline which belongs to burnt clay and to no other material, and their life history is still further recorded in the varied clouding and colouring of the fire. And the bricks are sensibly arranged without any unnecessary time wasted in making them exactly regular. The eye of the workman guides his hand without any mechanical aids, and so the work becomes a human document—becomes almost as characteristic as handwriting. And then when we consider the timber we shall find the same discernment in its treatment. In a material which has a distinct grain, and which gives us a distinct and characteristic surface when chipped with an adze or chisel, it seems that the real qualities of the timber can best be developed by such workmanship. Again, in the treatment of wrought iron, we find the forms of the metal chiefly valuable as illustrating the fact that though now cold and hard, in passing through the fire it was soft and ductile. In the plaster the same hint as to character will be given, and it will appear like a lava stream which has flooded the walls, flowed round the timbers, and so at last became frozen. And all the subtle differences of texture in surfaces and outline, arising from this kind of craftsmanship, will come about, not for the love of irregularity for its own sake but for the sake of expressing the individual character of each material. Anyone who has engaged in any kind of craftsmanship must have experienced that kind of will-force which a material, such as timber for instance, possesses. You may lead it gently in one direction, but only by force can it be made to go in another. The craftsman, then, can either impose his will relentlessly and crush the individuality of the material with a mailed fist, or he can allow the expression of its character. In the old work it was the latter method we shall find followed, and all the mouldings and carving in old oak, for instance, seemed to gain their chief value, not from any special beauty of line or contour, but from the way in which they seemed to explain and emphasize the qualities of the material. It is the same sort of commentary as we have noted in the building itself in relation to Nature. The old house seems to say, "All these fields and woods which surround me have a message and a meaning. That message and meaning I can convey to you for I am in the secret." And so the carved and moulded panel of some old oak chest: "Behold me; I am English oak. See how my knotted grain has deflected the chisel. I am subdued and disciplined to my place in the world, but my character and individuality still remains."

All these qualities of old work which I have endeavoured to indicate are not difficult to obtain. They arrive automatically if work is done simply and naturally. To smooth away all the character from a piece of oak till it might be mud, or cheese, or anything, is quite a tedious process, and indeed is generally the

outcome of pride in command over tools—the pitfall which seems always to await every school of craftsmanship. We must give up all such pride of mastery; for good workmanship, like good government, must seek to understand the true character of its subjects, and yield room for the due expression of that character. If then we consider the craftsman as the ruler of a kingdom, in which each material is given its appointed task and allowed in the doing of it the proper expression of its qualities, we shall find the cumulative result in the building, of little isolated tasks rightly done, beyond all our expectations.

It is difficult to put into words the effect of an old house of the craftsman period on the mind of the sympathetic observer. We may be moved to delight by pictures and all the stored treasures of the past to be found in our museums. We admire all these things, but perhaps go away from them with a confusion of the mind and a headache. We are dimly conscious that there is something wrong, and that art should not be jumbled into galleries and museums, but form the proper setting of our lives. But in the old house we find the real thing that our fathers knew. We are enveloped at once in an atmosphere of peace. We are snatched away from transitory frivolities and all the superficial unrest of modern life. The walls seem to breathe out healing virtue, and as we pass from room to room we recognise that here indeed is the mistress art, compared with which all other arts are vain.

In leaving the consideration of the craftsman period for that of the scholar period at the time of the Renaissance, we are taking the first step on the downward path which ended in the lowest depths of the Victorian era.

Fig. 12.—Cottages at Gidea Park, Romford. (View from Road.)

In the craftsman period, house building was essentially a creative art, and all its forms were the expression of definite functions. A beam was placed to carry weight, a buttress to resist pressure. But when the Renaissance introduced to our builders all the features of classic architecture, a new principle of imitative art was introduced. At first the impetus of the tradition of the guilds prevented any serious damage, and the quaint use of the new forms by the craftsman of England was not without its charm; while the prim scholarship of the style of building thus developed was saved from

dullness and pedantry by the human qualities of the earlier tradition. But still, by slow degrees, the whole business of building became hardened into formula; the creative artist gradually became specialised in the accessory arts, and the downfall of building as an art was complete. In the buildings of the craftsman period all the forms used were those which the creative intelligence of the builders had devised to meet the requirements of structure, without reference to buildings created for other purposes and other climates. The whole form of the plan was conditioned mainly by the building up of its component apartments in their required positions, and as the occasion demanded the building took upon itself various forms. But when the Renaissance came, and men began to look back and imitate externals, it became the custom to think of the house as a rectangular symmetrical box, in the four walls of which had to be packed the multitudinous apartments which a more advanced civilisation demanded. In the struggle which ensued, symmetry generally broke down somewhere, and it was necessary to help it out with the sham window and other devices. This kind of building was most at home in the town, where the rectangular outline of the plan was logical; but in the country the rambling and irregular forms of the earlier buildings were more appropriate and more in harmony with their natural surroundings. The main drawback to the Renaissance work, however, was that it destroyed the creative initiative of the craftsman. All the freedom and vitality which was the mark of the earlier work was strangled in the grasp of the classic pedants. Building, as the universal vernacular speech of the many, was superseded by architecture, as the stilted scholarly utterance of the few; and all the organised bodies of craftsmen became despoiled of their heritage of creative work, and became the mere lackeys of the designer of the building who lived in another world than theirs. The architecture thus developed was no longer the logical expression of actual structure. It was a matter of externals; and so all the realities of the building became degraded to the dismal science expounded in the current text-books.

In the craftsman period it was rare indeed to find any feature in a building which was not the immediate outcome of function. Utility was the foundation on which the whole structure was based, and though it soared above it in many expressions of fancy, the sure foundation was always there justifying its highest flights. But when the Renaissance led our builders to copy the external features of the buildings of Rome, the cart was put before the horse, and the particular function, instead of creating its own inevitable form, had to make the best it could of forms which had originally expressed quite different purposes. Once the habit of copying foreign buildings was established, it quickly tired of the buildings of Rome and passed on to Greek art. Then Gothic work was discovered, and duly imitated in its turn. And so our architects passed from style to style with growing dissatisfaction. Each new adventure became in turn old-fashioned, and it was always the latest enterprise which was going to be the right thing at last. But still the glory that was Greece and the soul of Gothic art alike proved too elusive to be captured. Each belonged to its own time and to no other, and found no place in the modern world. The great glory of Greek and Goth was that they created Greek and Gothic buildings. It was nothing to the credit of the modern architect to imitate these creations. He might as well have imagined he could emulate Shakespeare by copying a page from one of his plays.

And while our architects were busy with all these futilities, gradually whatever practical structural ability we were producing was specialising itself in engineering, while artistic genius was devoting itself to painting and sculpture. The building art became drained of its best blood, and the production of houses, the most vitally important function of the community, became, as it remains to-day, the almost exclusive field of the speculative builder. And as in the Victorian era the last breath of the earlier tradition expired, the English house touched its lowest depths. We have not to go far to find plenty of examples of these houses, with their dark basements and lofty reception rooms--harsh cold and repellent—without one touch of human handicraft. To follow the progress of house building through the nineteenth century is a sorry task. One is reminded of the old story of the tower of Babel, when the building was obstructed by a confusion of tongues. On the one hand was the architect, with his enthusiasm for reproductions; on the other, the craftsman without any enthusiasm at all. Architect and craftsman lived in different worlds, and spoke different languages; and so the architect always found in some disconcerting way that his modern house, built on the model of the old, was never the least like it. The old was always better, because it was

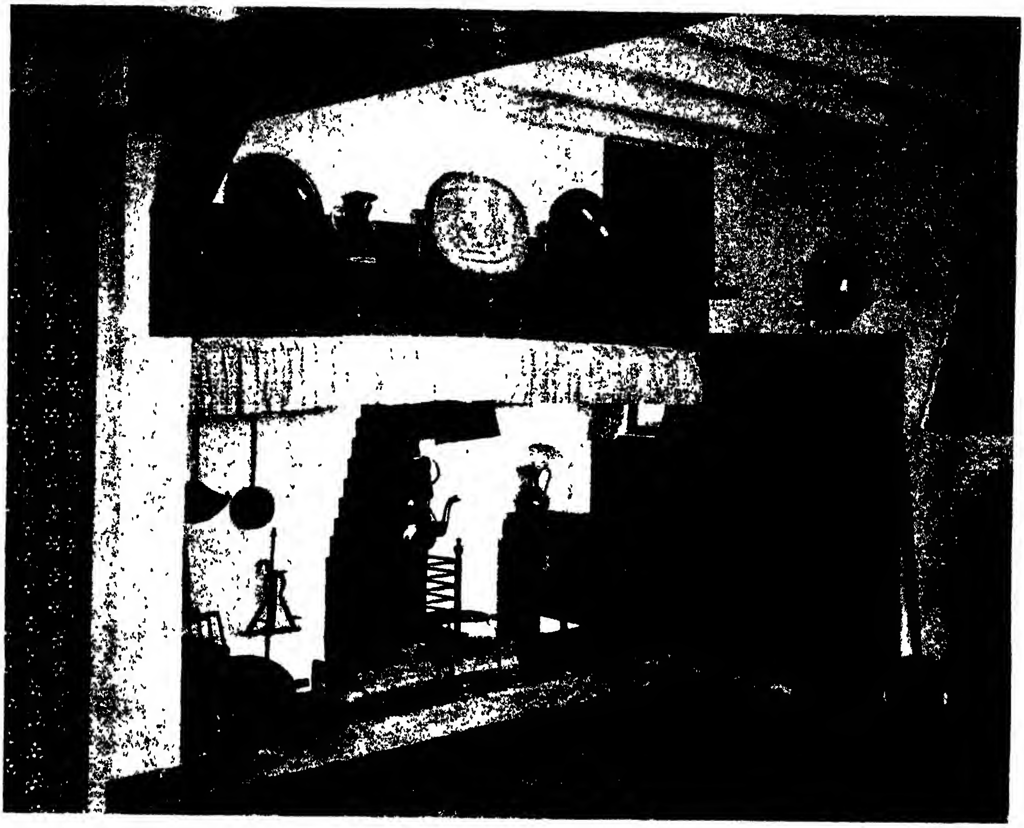

FIG. 13.—COTTAGES AT GIDEA PARK, ROMFORD. (Living Room Fireplace)

produced under entirely different conditions, and was a spontaneous and unique expression of its time.

I can liken the buildings so produced to nothing better than waxworks. They reproduced external forms, but could not supply the vital spark. The builders went through the motions of building, and gave us all the correct external forms. But they could not give us the one thing needful to make their dry bones live.

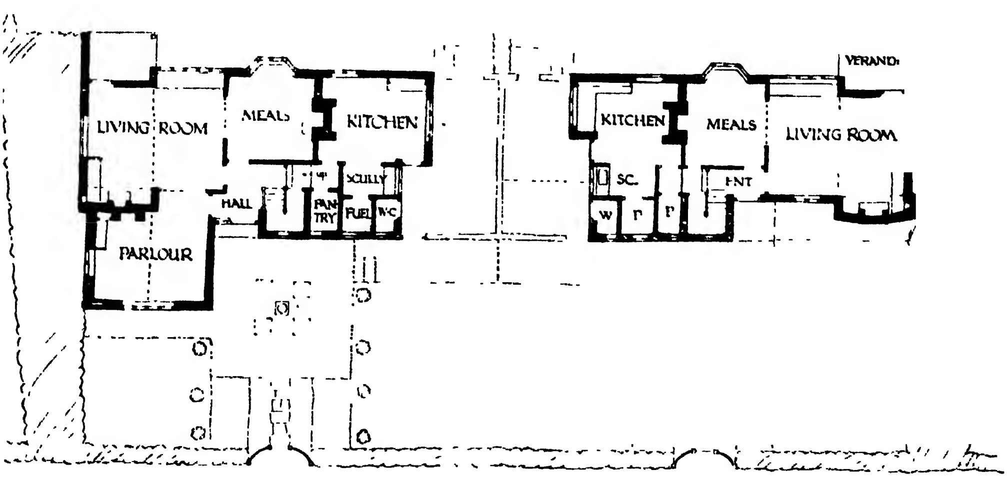

FIG. 14.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Textile Institute.—It cannot be said that the discussion upon education at the Huddersfield Conference of the Textile Institute exhausted all the views that manufacturers are known to entertain upon that subject. They are popularly understood to suffer from a certain illiberality of ideas, but it was a manufacturer who intervened against a scientist to prevent the Institute from seeming to asperse the advantages of a classical education. The interposition gives a reminder, if it were needed, that the manufacturing classes include men of widely different antecedents and outlook upon life. Another manufacturer, speaking purely of cases within his own knowledge, avowed that three out of four of the parents who take their children earliest from school, have no genuine need of the money brought in by their offspring. A discussion ranging over the higher, lower and technical education failed to show that any one coherent idea of how these matters should be administered or reformed commands the industrial m'nd. The arguments that education is more necessary now than ever; that money must not be grudged to it; that changes must be made and a multiplicity of counsellors called in, are of course not new ones. They were advanced with emphasis and cogency, but a more detailed examination of the considerations involved might reasonably have been looked for. There is nothing, however, to suggest that the Institute has done with the subject, and it is the fact that the new problems and certain definite proposals engage the minds of those who do the collective thinking for the textile trades.

Industrial Education.—It is at all events probable that manufacturers will continue to follow diverse courses in the education of their sons; some sending boys destined eventually for the mill to the public schools and old universities, and others equally able to support the cost of a liberal education putting their boys into the mill at some such age as seventeen. Good industrial and commercial results have been obtained by both methods, and both of course have furnished disappointments. A not too distant analogy can be found in the action of those who send their sons for a few years to the technical schools or new universities, and the others who insist upon mill training by day and school training by night. Where so much latitude prevails general rules are not easy to draw, but it would seem that, upon the whole, manufacturers are disposed to look on mill work as the larger part of an industrial education. In one way and another manufacturers have had a good deal to do with the shaping of the technical education imparted in the textile districts, and for any defects in it they must bear a share of the blame. Educational systems being in their nature things in which final perfection is never reached, dissatisfaction with them can never be absent. Late years have seen a great addition to the plant and apparatus of the textile schools, and a great increase in the number of persons receiving tuition. What is not so clear is that quality has kept step with quantity. Judgment is not easy to make, and certainly cannot be formed upon a consideration of *matériel* alone. It would appear that in technical, no less than general education, the individuality of the teacher counts for a very great deal, and it may be the case that individuality has less play in these days than in times when technical education was less systematised. The opinion is one that is found to exist.

Industry and Finance.—The conflict between industry and finance is not so marked and open as the old one between labour and capital, but it is responsible for an occasional explosion of feeling. The conflict is the same, although the plane is a different one. The industrialist, or workman, is conscious of the worth and necessity of his work, and the financier, capitalist, or shareholder looks out on a horizon bounded simply by profits. The conflict is passably reconciled where the parts of captain and capitalist are doubled by the same person, and it breaks out the more clearly the more the separation is defined. There are no grounds for thinking that the old relations between working partner and sleeping partner in the private firm were untinged with acrimony. Assuredly there have been moments of tension between the private employer and his backer, the manager of the bank. The financial press has some responsibility for a bitterness of feeling exhibited between managers of industrial undertakings and public shareholders. A tone of insolence, even when diluted by tell-tale signs of ignorance, does not tend to promote cordiality of feeling, and it is undeniable that grossly contemptuous airs have been shown towards men who have for any reason failed to report the accustomed dividend. Sir William Mather, a week or two ago, spoke of the misfortune that brought industry within the control of those who only understood stocks and shares, and could only decide by dividends whether a company was worth continuing or not. The words are the new paraphrase of the intense conviction in textile quarters that "brains are worth more than brass."

The Enemy's Raw Materials.—Such information as filters through from Germany goes to show that the quest for new textile fibres of home production has been fruitless. The hop-bine, the willow-weed, nettle fibre, broom, and the rest of them, have apparently proved as unsatisfying as might have been fairly expected, and the later rumour that a means has been found of spinning wood fibre can be received with all reserve. A German mill-manager who has been driven back upon the wisdom of the ages, counsels his countrymen to plant hemp and flax, the one as a substitute for jute and the other for cotton. Given seed, both can be had by waiting, and shift can doubtless be made to convert them into yarns and fabrics

generally less suitable for their purpose than the originals. A noticeable silence has come over the reporters upon the condition of German textile industry, and in view of the increased restrictions upon the sale of textile goods the inference is that the suffering is growing extreme. Reliable reports state that a prepared cellulose obtained from wood and called "lignin" has a large sale in Germany in place of the usual surgical lint of absorbent cotton-waste. In Sweden also a cellulose wadding for wounds is being made in sheets resembling crinkled paper. Probably enough, cellulose yarn made by twisting ribbons of paper finds a more extended employment in Germany than it did when jute was available in its place. The increased pains taken by the British Government to prevent raw or manufactured textile supplies are reflected in one trifle that has not been reported, as well as in the regulations which make it difficult to export cottons to European ports. The woollen cloths sent out to Berlin from this country for wear by British prisoners are of a colour to make them useless to German troops. These goods have been dyed black.

Dyestuff Manufacture.—A committee has been formed, representative of dyers in all trades, to consult with the Government departments responsible for the provision of dyestuffs, and for the supply of materials and reagents necessary for the manufacture. New makers of dyestuffs are springing up in some number, and the suggestion is abroad that various new and large works erected primarily for explosives will ultimately turn to the colour trade. A site for the new factories of British Dyes, Ltd., has been found on 250 acres of land at Huddersfield, where there are good rail and water transport, soft and abundant water, and adjacent supplies of coal. Contracts for construction amounting to £250,000 have been let, so that in one way and another the dyeware supply is being advanced. Perhaps for a long time to come there will be a scarcity of particular colours, a scarcity which exhibits itself conspicuously in matters of price. It is the case, for example, that a cotton dyer, wanting an especial colour for which he habitually paid 10½*d.* per lb., had to pay 45*s.* per lb. for his material.

Systems of Price-Maintenance.—Price-maintenance compacts between manufacturers of textile goods are not wholly unknown, but for special reasons they are not as common, or perhaps as necessary, as in some other trades. The makers of goods see something of the manœuvring of others who are parties to bargains aiming at keeping up prices to them. On the whole, their objection may be less to the successful scheme, always assuming it not to be extortionate, than to the compact which results in letting some have services or supplies at more favourable rates than others. There is, at any rate, a running warfare between manufacturers and the members of various price associations. One of the commonest ways in which these undertakings are circumvented is by the all-round price. The association issues its quotations showing different prices for different services, and the disloyal member offers to undertake all the work that is sent to him at a fixed or median price. The details are beyond supervision, and the customer who bargains well fares better than the one who pays the scale rates. Even allowing for such breaches, it is possible that the compact is better than none at all from the standpoint of those who enter into it; but the process of breaching is self-destructive in the end. In the United States an alternative method, which may not be actually bomb-proof, has been introduced with some success. The members of the ring quote prices as they think fit, and communicate their quotation to a secretary who circulates them throughout the membership, or even throughout the trade. The method seems, at first blush, to facilitate matters for those whose simple system is to take business by offering terms a little lower than any others. Pursued far enough that process leads to mutual extermination and it is necessary to take into account the counter-attraction of the market price. In performing the same or better services than A, the competitor B is not satisfied permanently unless he obtains at least A's price for the same work. There is a competition to secure good prices that is to the full as real as the competition to obtain work, and if this open-price system survives a protracted trial its success must be attributed to the opportunity given to upward as well as to downward driving. The operation is not actually more wonderful than that taking place in auction rooms, where buyers, whose common interest is to buy cheaply, find themselves forcing up prices against each other.

OBITUARY.

Sir Thomas Fowell Buxton, Bt., G.C.M.G.—Sir Thomas Fowell Buxton died on October 28th at Colne Cottage, Cromer, the residence of his son, Mr. Noel Buxton, M.P. He was born in 1837, and was educated at Harrow and Trinity College, Cambridge. Upon the death of his father, Sir Edward North Buxton, he became third baronet in 1858. He entered Parliament as member for King's Lynn in 1865, but he only retained his seat till 1868. For many years he took a deep and active interest in the work of the British and Foreign Anti-Slavery Society, and was its President since 1899. Like his brother, Mr. Edward North Buxton, he was a Verderer of Epping Forest. He was a warm supporter of the Volunteer movement, serving as Colonel of the Second Tower Hamlets from 1864 to 1883, and as honorary Colonel from 1884 to 1903. In 1895 he was appointed Governor of South Australia, an office which he held till 1898. In 1899 he was created a G.C.M.G. in recognition of his services in the Commonwealth.

Sir Fowell's connection with the Royal Society of Arts dates from 1875, when he took the chair at

a meeting of the African Section, which has since become the Colonial Section. The paper on that occasion was "Livingstone's Discoveries in Connection with the Resources of East Africa," by the Rev. Horace Waller. From that time Sir Fowell continued to take a warm interest in the work of the Society. He became a member in 1879, and in 1903 was elected to the Colonial Section Committee, on which he continued to serve to the time of his death. On several occasions he presided at the Society's meetings, and he frequently took part in the discussions, being particularly interested in subjects connected with Africa and Australia.

GENERAL NOTES.

German Trade in India.—The *Englishman* gives some particulars of a scheme set on foot in some native states of Central India to rescue the lac trader and some of the hide traders from German and Austrian clutches, and to raise the standard of Central Indian hides which, under the description of Rewah hides, had a bad name. The scheme has received the sanction of the Government of India. The new organisation is the result of several years' hard work, and is already making its way in the home markets, though to nothing like the extent to which it should presently develop, for the organisation now covers the territories of eight native states of some 10,000 square miles, an area considerably greater than the principality of Wales. In view of the needs of tanners in England, the Association is already busy on tanning products, of which there are unlimited quantities in Indian forests. The states concerned in the undertaking are Nagod, Manihar, Baraundha, Jaso, Taraun, Panna Chhatarpur, and Datia in Baghelkhand and Bundelkhand, while Ajaigarh and Bijawar will probably join. They have formed a company named the "Esociet," which is short for "Eastern States of Central India Export Trust," with a capital of three lakhs. The states are represented on the board of directors. "Industrial development," says a memorandum on the scheme, "is recognised as one of the great needs of this country, and it is confidently believed that this scheme will be of immense benefit to the states concerned, and particularly to the smaller states now solely dependent on agriculture, whom it should raise to comparative affluence and relieve of much of the anxiety inseparable from the present precarious source of their income."

The Canals of China.—The canals of China are one of the wonders of the country. The Grand Canal, which is nearly 1,000 miles in length, was begun in about the sixth century B.C., but was not completed until 1283 A.D. Of late years this magnificent waterway has been neglected, and its value for navigation purposes has greatly diminished. There is no reason, however, if adequate funds were provided and judiciously expended, why the Grand Canal should not again become an important factor in transportation in China. While the Grand Canal appeals to the imagination by reason of its great length, the canal systems of the provinces of Chekiang and Kiangsu are really more wonderful. In an area ·175 miles by 160 miles there are no less than 25,000 miles of canals. Travellers by the Shanghai-Nanking Railway and the Shanghai-Hangchow Railway are amazed by the number of canals that are crossed each mile. Along these flows a steady stream of traffic, sometimes a number of heavily laden house-boats towed by a diminutive steam launch, sometimes an old-style craft propelled by a stern-oar. More than 4,000 years ago Yu, who afterwards became Emperor, inaugurated the system of canalisation that obtains in China to-day, and compensates for the absence of roads. Even when the vast programme of railway construction that has been decided upon is carried out, the canals will continue to be a most important factor of traffic between districts. They will not compete with, but feed the railways.—*Manchester Guardian China Number.*

MEETINGS FOR THE ENSUING WEEK.

Monday, November 8...Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. E. B. Collier, "Notes on the Designing of a New Brewery."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Opening Address by the President, Mr. J. J. Hanson.

Tuesday, November 9...Photographic Society, 35, Russell-square, W.C., 8 p.m. Presidential Address.

Zoological Society, Regent's Park, N.W., 8.30 p.m. 1. Dr. G. E. Nicholls, "Some Notes upon the Anatomy of *Rana tigrina*." 2. Dr. J. C. Mottram. (*a*) "The Distribution of Secondary Sexual Characters amongst Birds, with relation to their liability to the Attack of Enemies", (*b*) "Some Observations on Pattern-blending with Reference to Obliterative Shading and Concealment of Outline." 3. Mr. C. Boden Kloss, "On a Collection of Mammals from the Coast and Islands of South-east Siam, with an account of the Fruit-bats by Dr. Knud Andersen." 4. Professor W. J. Dakin, "Fauna of West Australia.—III A new Nemertean—*Geonemertes dendyi*, sp. n.—being the first recorded Land Nemertean from Western Australia. IV. *Palæmonetes australis*, sp. n., being the first record of the Genus in Australia."

Wednesday, November 10...Automobile Engineers, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. J. H. Dickenson, "The Choice of Steel for Use in Automobile Construction."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Professor L. W. King, "Recent and Future Work in Mesopotamia."

Chadwick Public Lecture, at the Royal Society of Medicine, 1, Wimpole-street, W., 5.15 p.m. Mr. A. Saxon Snell, "Emergency Military Hospital Construction."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Professor W. de la Mare, "Ghosts in Fiction."

Thursday, November 11...Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mrs. J. H. Harris, "Tramping and Canoeing in Central Africa."

Auctioneers' and Estate Agents' Institute, 34, Russell-square, W.C., 5 p.m. Mr. S. A. Smith, "War Risks to Property."

Friday, November 12...Astronomical Society, Burlington House, 5 p.m.

Journal of the Royal Society of Arts.

No. 3,286. VOL. LXIII.

FRIDAY, NOVEMBER 12, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

In pursuance of the announcement in the Examination Programme for the current year, the Council have decided not to offer the usual money prizes in connection with the examinations for 1916. They are, however, enabled, by the liberality of the Court of the Worshipful Company of Clothworkers, which has renewed the grant it has hitherto voted for certain special prizes, to continue the offer of Medals under the usual conditions.

As there will in future be no first or second prizes, the order of the award of the Medals will be stated. The number of those awarded in the larger subjects may be slightly reduced.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Sixty-Second Session will be held on Wednesday, November 17th, when an address will be delivered by DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council. The subject of the Address will be "English and German Methods Contrasted." The chair will be taken at 4.30 p.m.

The following arrangements have been made for the meetings before Christmas:

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.

NOVEMBER 24.—SIR EDWIN PEARS, "Constantinople, Ancient and Modern." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

DECEMBER 1.—THE MASTER OF CHRIST'S COLLEGE, CAMBRIDGE (Arthur Everett Shipley, Sc.D., F.R.S.), "Insects and War." SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., will preside.

DECEMBER 8.—LIEUT.-COLONEL W. A. TILNEY, 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

DECEMBER 15.—J. JEF. DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." (With illustrations.)

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

NOVEMBER 30.—SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica, "Recent Developments in Jamaica: Internal and External." SIR HENRY A. BLAKE, G.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:

DECEMBER 16.—C. C. MCLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas:—

LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., "Optical Appliances in Warfare."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:

February 1, March 21, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.: —

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." Three Lectures.

Syllabus.

LECTURE I.—NOVEMBER 29.—Comparison of optical with ordinary glass—Defects and properties of glass for optical purposes—Transparency—Colour—Bubbles and defects—Striæ or veins—Internal strain and annealing—Hardness and durability—Testing of optical glass—The optical properties of glass—Refraction and dispersion—Their relation in crown and flint glasses—Glasses introduced by Schott and Abbe—Partial dispersions and the secondary spectrum—Apochromatic glasses and lenses.

LECTURE II.—DECEMBER 6.—History of optical glass manufacture—Fraunhofer, Guinand, Feil, Bontemps, Chance—Schott and Abbe—Hopkinson and Stokes—Efforts in England. The present method of optical glass manufacture—The furnace—The pot—Production and treatment—The process of melting and fining—Stirring and finishing—Cooling—Breaking up, selecting and moulding—Annealing—The final form of the glass.

LECTURE III.—DECEMBER 13.—The present process of manufacture—General difficulties—Costliness Cost of the pot—Time of production—Cost of melting—Raw materials—Low yield of good glass—Risks of the process—Risks of loss during melting Failures due to striæ—Risks of contamination—Errors and variations of optical constants—Range of glasses demanded by opticians—Small quantities required—Need for large stock of optical glass. Special difficulties in England—Cost of raw materials and of labour—Refractories. Special difficulties connected with "new" glasses—Their chemical activity—Action on pots—Absorption of colouring impurities—Attainment of extreme optical properties. Need for research—The general problem—How to make good optical glass—Necessary improvements in pots and refractories, and in furnaces and methods of working—Utilisation of new materials and electric methods—The special problems relating to individual types of glasses—Optical and other properties to be realised simultaneously—The limitations of possible glasses—Optical properties of crystalline media—Future possibilities.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April, 3, 10.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The lecturer and subject will be announced later on in the *Journal*.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Monday afternoon, the 8th inst. Present:—

Sir Steyning William Edgerley, K.C.V.O., C.I.E., (Chairman of the Committee), Sir Arundel T. Arundel, K.C.S.I., Sir M. M. Bhownaggree, K.C.I.E., William Coldstream, B.A., I.C.S. (retired), Sir William Duke, K.C.S.I., K.C.I.E., Right Hon. Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E., Sir Frederic W. R. Fryer, K.C.S.I., Sir Frederic S. P. Lely, K.C.I.E., C.S.I., Sir John Ontario Miller, K.C.S.I., R. A. Leslie Moore, I.C.S. (retired), Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with S. Digby, C.I.E. (Secretary of the Section).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

HOUSE BUILDING: PAST AND PRESENT.*

By M. H. Baillie Scott.

Lecture III.—Delivered March 29th, 1915.

In my last lecture I tried to indicate some of the qualities of the building of the past in this country, emphasizing the fact that building was then almost invariably an added beauty to the world of nature. If we now turn from these old buildings to those of the modern world, we shall find a radical change has taken place in this respect. Building, instead of being, as a matter of course, an adornment of the world, has now become generally recognised as a deplorable but necessary disfigurement. When some country district is invaded by modern houses, we all lament the spoiling of its beauty. So it comes to this. Old building beautified the world; modern building spoils and disfigures the world. I know there may be those who do not think this important, but I believe it is quite wrong to think of beauty in building as a kind of luxury we can do without, which only affects the susceptibilities of a few fastidious artistic persons. If that were the right view, it would ill become me to be speaking of such matters in these days. But my chief concern about building is not so much from the point of view of the observer as of the producer. And I believe that beauty in building is the natural outcome of healthy and happy work, and that while the production of beauty naturally is a sign of health of the spirit, the production of ugliness is a sure sign of disease.

I am, of course, aware that, besides the commercial buildings of to-day, there are some brave attempts now being made to build in a better way. These attempts are, however, quite isolated and sporadic, and count for little in comparison with the bulk of modern house building. And those who attempt to apply right principles to modern building find their way beset with difficulties, for of building considered as an art the modern builder knows little. His whole outlook, and the whole training of his men, has been towards an ideal of mechanical perfection. The best kind of brickwork, from his point of view, is a wall of perfectly regular and evenly coloured bricks; the best kind of roof tiling consists of tiles of exactly similar shape, size and colour, in faultlessly even rows. To ask the modern workman to throw over these ideals is to injure the only pride he has in work, and if he concedes his point it is but indulgently to humour what he considers an amiable weakness. It is usually only the younger workmen who are capable of understanding and realising the greater possibilities which are revealed in building when once the ideal of regularity for its own sake is given up. But any real reform can only be gained by a more intelligent teaching of building construction, and a recognition of the possibilities of ordinary craftsmanship. If one refers to any of the ordinary text-books placed before the student, the crafts are displayed with a stupid disregard to anything more than dull material considerations. A certain formula is given for the construction of a floor: joists of a certain regular size are to be placed a certain number of inches apart. Below them the plaster ceiling is fixed, and above them the boards. That is the way, and apparently the only way, to make floors. But if we visit an old house we shall find these joists placed with a fine disregard for exact spacing or equality of size. We shall note how the slight undulation of their outlines expresses the character of timber and suggests the lines of the grain. The plaster is fixed between these joists, which are left visible and are themselves supported by beams, which are again in their form, surface and outline, full of suggestion of the character of the material, so that they convey to us a hint of the fact that though now subdued to the will of man these beams had once been living trees of the forest. It is also always assumed, in these text-books, that the simplest way of doing a piece of work is the worst, and that really high-class work is distinguished by unnecessary elaboration. The general idea to be gathered from the building text-books is that we have, first, the rather plain and dull business of common building, which, as it develops in elaboration and ornateness, ascends in the scale till at last it becomes sufficiently complicated to be called architecture. It is on such principles as these that our architects and builders are trained; so that to learn anything about the art of building it is necessary for most of us to begin by forgetting everything we have been taught, and to pick up, as we can, mostly from old work, the general principles of the right kind of building.

The influence of machinery on the handicraft of building no doubt largely accounts for the

* All the houses illustrated are designed by the author.

mechanical ideals of the modern craftsman, although it would seem it ought to have the opposite result. For the craftsman should say, "Here am I engaged on a mechanical task. It might be easier to lay these bricks by machinery; but since they are to be arranged by a human being, would it not be well for me to put something into the work which no machine can compass?" Machinery, then, has its uses in showing us the futility of mechanical art, and emphasizes the importance of the direct, personal touch of the artist. It is well that machinery should be used in the service of man for executing those tasks which are outside the proper scope of handicraft. But in all machinery there seems to lurk a malignant imp, which imposes its will on us, narrowing our whole conception of the universe to a mechanical standard, and making us in the end the slaves of the monster we have created. On this subject of mechanical art, the eloquent words of John Ruskin may be quoted. He says: "It does not become our immortality to take an ease inconsistent with its authority, nor to suffer any instruments with which it can dispense to come between it and the things it rules; and he who would form the creations of his own mind by any other instrument than his own hand would also, if he might, give grinding organs to Heaven's angels to make their music easier. There is dreaming enough and earthiness enough and sensuality enough in human existence, without our turning the few glowing moments of it into mechanism; and since our life must at the best be but a vapour that appears for a little time and then vanishes away, let it at least appear as a cloud in the height of Heaven, not as the thick darkness that broods over the blast of the furnace and rolling of the wheel."

Fig. 15.—"The Cloisters," Avenue Road, N.W. (View from Road.)

One of the main differences between modern building and that of the past is its marked incoherence. As such it faithfully reflects the unrest of modern life. In the living ages of art in building, we may compare its life force to the chlorophyl which colours the leaves of

the trees. This chlorophyl has now become degraded, as a botanist would say, and individuality runs riot. The broad stream of modern building is of that peculiarly repugnant commercial kind which thinks to use art as a kind of bait. Instead of the confessed brutality of Victorian building, we have the picturesque villa, with its long, sloping roofs and other travesties of the features of the old English cottages. And it would appear that these things are gratefully accepted by an unsuspecting public. The house is given a ridiculous name, and filled with artistic furnishings, and no one seems to suspect there is anything wrong with it. Picturesqueness in the old village is right, because it is the natural outcome of requirements, and has not been deliberately aimed at for its own sake. It hardly appears to have been "designed," but to have merely inevitably occurred. And if we consider the quality of the building in the modern garden suburb, we shall find all the subtleties of the traditional craftsmanship of the past have disappeared in the modern work, and the cottages are run up by the help of labour which has lost all power of self-expression. Much, of course, must depend on design; but workmanship is vital. The man who shapes the timbers and lays the bricks supplies, at first hand, his contribution to the final appeal of the building, and can make or mar it. We should find no difficulty in recognising such an obvious contention as this in any art properly accredited as such. We know that each stroke of the painter's brush, and each touch of the musician's hand, goes to build up the final beauty of a picture or a sonata; but because we have forgotten that building is an art we have come to think of its processes as merely mechanical. In the meantime our architectural students are not interested in building at all. You will find them engrossed in the ancient architecture of Greece and Rome, and making ambitious schemes for royal palaces and public memorials. Not long ago there appeared in the architectural papers the students' designs submitted in a competitive exercise of their skill. And what was the subject? Was it a cottage or country house? Perish the thought that they should concern themselves with such trivialities! No, these beginners must begin at the top. They were to design a monument to commemorate the bringing of water to a town. This design was quite seriously undertaken, and resulted in variations on that particular kind of fatuity which consists of innumerable flights of steps leading nowhere in particular and culminating in a central sculptured imbecility which not even all the facilities provided in the way of steps would induce one to approach. I do not wish to reflect in any way on the ability shown by the students in these designs: I would merely wish that it were better directed in solving the practical problems of the day.

The difficulties in the way of the practice of the art of building in these days, due to the mechanical training of the architect, ruling his lines on a board, and the bricklayer, ruling his lines on the wall, are only a part of the artificial obstacles put in the way of the artist in building. He has in most districts to face also an arbitrary, vexatious and irrational set of rules, and to fit his building to the Procrustean bed of the building by-laws. I cannot now enter into a detailed exposure of the illogical absurdity of these enactments. They interfere either too little or too much with the liberty of the subject. They set forth cast-iron regulations for the height and window areas of bedrooms, for example, but they cannot prevent the windows being covered with curtains, as they generally are, and they cannot prevent the householder sleeping in a cupboard under the stair, or in the coal cellar if he has a mind. If we are to be dragooned into healthy ways of living, it should be done consistently or not at all, for the application of the building by-laws in many cases defeats the end in view. For instance, in attic rooms it is usually enacted there must be at least 5 ft. height at the sides. The application of this rule to the ordinary attic means a reduction in the cubic capacity of the room.

I think, if I were asked what is the most satisfactory feature in modern house building, I should say it was the scaffolding. In constructing it we find there is a recognised tradition, and a rough-and-ready simplicity and honest adaptation of means to ends — all the qualities in short which, in the modern building it surrounds, are so conspicuously absent. It evidences the fact that the pursuit of beauty in building is so often almost as vain as the pursuit of happiness in life. Both alike are by-products, and arrive as a reward for doing the right thing in a simple straightforward way. As an example of the qualities of scaffolding, I may mention the forest of spars and knotted rope which just now encloses the Albert Memorial; and in passing it to-day I was led to hope that the work which is being done there may not be completed too soon.

Since I began this course of lectures on house

building, the inadequacy of my treatment of the subject has been brought home to me by various communications I have received with reference to several practical aspects of the question. With regard to many of the latest inventions in the practical appointments of the modern house, I share the common English quality of requiring that some one else shall be the first to experiment with them. I can at least say that I am a believer in the use of gas for cookery—if not entirely, at least as a supplement to the kitchen range; and, for the latter, the use of anthracite as a fuel has many great advantages. In these adjuncts of the house, however, I can never understand why it is necessary to make such things as kitchen ranges and stoves and radiators so unnecessarily ugly, and why we should not have in them some of the simplicity and beauty of design in casting which we find in the old Sussex cast-iron work, for instance. I believe the only well-designed kitchen range I have seen, from this point of view, is, alas, made in Germany. Hitherto, I have dwelt at some length on the vital importance of workmanship to house building, because that seems to me to have been most neglected and misunderstood. I now propose to say a few words on a subject equally vital.

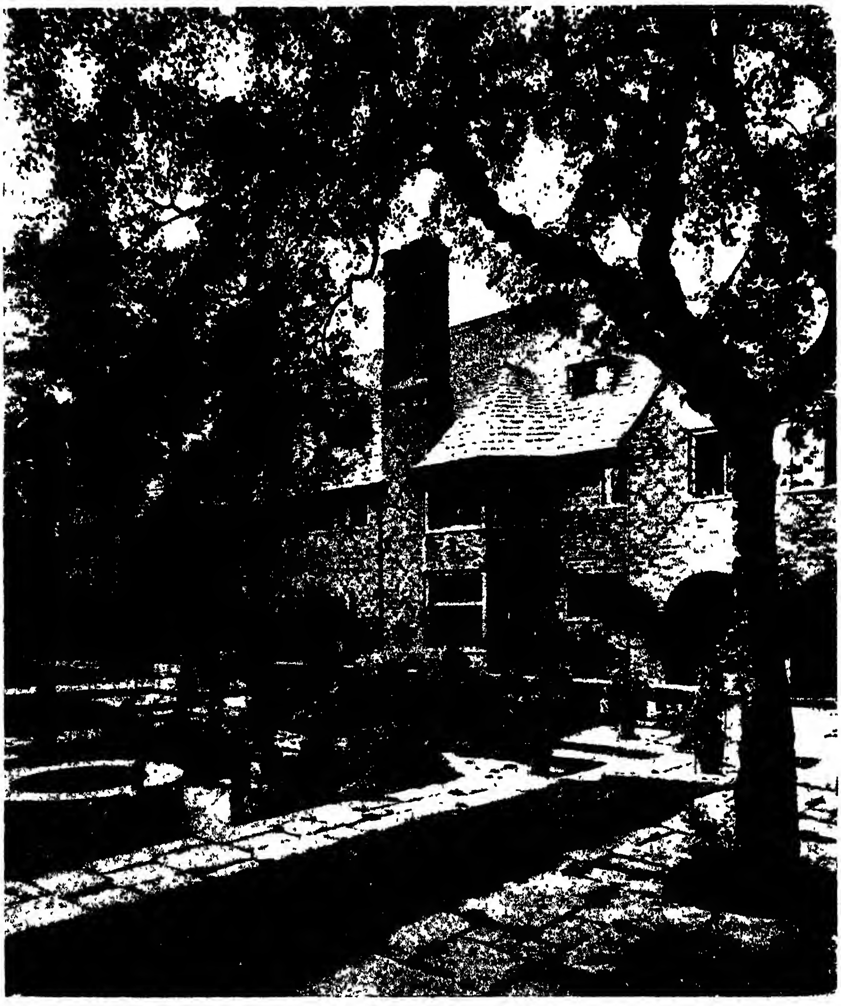

FIG. 16.—"THE CLOISTERS." (The Garden Front.)

The importance of proportion in the design of houses can hardly be overestimated. It is the fundamental thing. It is all the more unfortunate, then, that it eludes definition and explanation. It is a mystery and must remain so. In speaking of proportion as applied to the house, I mean by it not only the shapes

of its masses and the dimensions of its apartments, but also the relative sizes of all the parts of its structure. Used in this sense, proportion is often described as "scale," and a certain feature in a building is said to be "out of scale" when it is disproportionate. Not only in building, but in all the affairs of life a proper sense of proportion is of great value. To discern the proper significance of facts in relation to other facts without distortion is the mark of a well-balanced mind. The man who is obsessed with some idea which obscures his vision of the real facts of life is condemned as a faddist and a crank. Translated into terms of building, such an attitude would be represented by a house which is all bay window and staircase. And how disproportionate are the views of so many on the question of house building! One is all for the artistic, for quaintness and picturesqueness, without proper recognition of practical functions. Another is all for sanitation. He would have no corners to his rooms, no foothold anywhere for dust; one might imagine he would protest almost against the existence of houses at all, so that there would be no place for dirt and dust to collect. Then there is the light and air specialist, and the logical outcome of his attitude would make each house a little Crystal Palace. Or again, the labour-saving crank, whose ideal state would involve complete bodily inactivity, so that instead of performing the ordinary work of life one would be driven for health's sake to resort to some kind of physical drill to replace the healthful activity we have relegated to the machine. In such a welter of conflicting and disproportionate ideals we must try to hold a proper balance, and to look at things broadly and sanely; and the best houses I know are those which bear the stamp of a kind of inspired common sense, and contrive to weld into one the beauty of the old house and the practical contributions which modern science has made to domestic life. Without suggesting any mechanical rules of proportion, it may be at least safely affirmed that masses of structure which are long and low and broad-based convey the idea of calm and tolerant breadth of mind and wise humility, while buildings which soar high on narrow bases suggest ambition and aspiration. Each has the defects proper to its qualities, and as the broad-minded philosopher is apt to miss the significance of the higher flights of the soul of man, so the aspiring devotee may be narrow in his judgments. But, apart from such generalities, the general principles of proportion are to be felt rather than reasoned about, and a sense of proportion is to be gained by a study of good examples in the past, where the instinct for such matters was so unerringly fostered by tradition.

It must always be remembered that art in the past was not the highly specialised matter that it is to-day, and was concerned with practically all the activities of man. In modern practice, the painter recognises the value of relative proportion in the various parts of his picture, and he knows how the qualities of each colour and tone are modified by other colours and tones; but this sense of relative proportion with him stops short of the picture frame, which effectually cuts off the picture from the outside world, in the same way that the artist himself in the modern world is disassociated from the general field of human activity. But when building was the mistress art, and all other arts combined with the single idea of producing beautiful buildings, when the house was not merely a shelter for art treasures but itself the art treasure, then the same sense of relative proportion, now practised in the confines of the picture frame, spread itself over the world, and so the house was in harmony with nature and with other houses, and the furniture and ornaments were duly related to the house. How strange in such a world would have appeared the modern picture gallery, or the modern museum, in which art now takes refuge from life! In the picture gallery the walls are not adorned by decorative painting, but covered with isolated competing individualities; and in the museum all the ordinary appliances of life in the past are found divorced from their place and function and condemned to idleness, like able-bodied paupers on a bench in the workhouse of the arts. In the past all this painting and all these art treasures found their places as the normal setting of life in the houses of the people. There was no need for the picture gallery or the museum, for the whole world was a museum in which all the appliances of domestic life were both serviceable and beautiful.

In giving practical illustrations of the general principles of proportion in building, it will be well to consider first the design of the cottage. Here the building is necessarily a small one, and all its features must be small too, and the whole conception reduced in scale; and if this is done consistently and completely, in spite of smallness there will be no sense of disproportion. If, however, a window is made too large in scale, or the staircase developed as an artistic feature, or if a desire for a lofty ceiling

is allowed to obtrude, the whole modest balance of the building is upset, and the cottage becomes an abortive villa. And in the larger houses a like proportion is necessary, and the smallness of parts so desirable in the cottage often becomes pettiness when applied to larger houses, and in all no single feature stands by itself on its own individual merits, but can only be judged in relation to the whole building.

FIG. 17.—"THE CLOISTERS." (The Hall.)

As a starting-point in designing the modern house, we have all the work of the past to guide our choice, which, broadly, will lie between two types of what may be called the "craftsman," or romantic house, and the "scholar," or classic house; the house built on Gothic principles and the house built on Renaissance principles. The main difference between the two is that the Gothic work makes the constructive features of the house itself the elements of its appeal: it is a piece of building art to which any other decorative arts that may be introduced are subordinate. The beams of the ceilings are visible and the framing of partitions. We can read everywhere the story of the structure which gains a kind of individuality and reality. But in the Renaissance building, beauty is only skin deep; structure is everywhere concealed by superficial casings, walls and ceilings are coated with plaster, and all the structural features of the house hidden, while the interest of the rooms is centred on fabrics, pictures and ornaments. The main interest is transferred from the house itself to its accessories, and the house tends to become a convenient sort of box for sheltering people and their belongings—a box which may have

its external adornments and trimmings, but which no longer relies on the realities of structure for its significance as an essay in the builder's art. The main quality of the craftsman building is that it is elastic and accommodating. Windows and doors can be placed where they are wanted and the whole effect is natural, unaffected and homely. It kindles the imagination, and is full of the mysterious charm of romance. The classic house represents a statement complete and finite. It is a conscious piece of art which has been definitely arranged from the outside - not the natural outcome of internal requirements. It seems to challenge our regard and demand our homage. There is no escape from the insistence of its façades. But the craftsman house is more subtle in its appeal. It is casual; it rambles and dissembles; and only when we have entered the wide, low doorway, and become steeped in the deep and silent influences which breathe from its walls, do we begin to realise the potency of its charm. I must confess to a preference for this earlier building art; but it must be admitted that the classic house, on grounds of expediency, has much to recommend it in these days. Relying as it does more on design than on craftsmanship, it does not suffer much from machine-made mouldings and mechanical workmanship. Its parts might be standardised and made in a factory. Divided as it is into rectangular plastered boxes, it is easier to build under modern conditions, and it seems to express very well the kind of occupant whose ideals consist in a strict observance of the routine of life. If you can appreciate the mystery and magic of the earlier houses, and if you can feel the unfathomable depth and the warmth of their appeal, I doubt whether you will be quite satisfied with the Renaissance house, although its dignity and reticence is something to be thankful for. It is scholarly correct, and in good taste, but somewhat trite and shallow. It may be urged, however, that, as a starting-point for the modern house, we need not limit ourselves to the two types of old English house I have mentioned—the Gothic and classic. There are certainly the houses of other countries to be considered, although most of these can, in their principles, be referred to the two types I have mentioned. Of these, the Dutch houses have already been to some extent naturalised in the eastern counties of England; the Italian villa, as seen through Victorian spectacles, has hardly proved a successful model for the English house. The Swiss houses, delightful as they are in their own country, would only be suitable for ours if we could import the Alps as well. All these and many other ancient types of houses may be studied and inwardly digested, but not imitated. And then again we may fling away the past altogether, and devise the modern house as an expression of modern needs without any reference to the work of our fathers and other people's fathers. This scheme seems to open out a fascinating prospect. But building is such an old art that it is obviously foolish to cast aside all the garnered experience of the past. Let us hold fast all that has been well done, whatever bad work we may reject. Instead of cleaning the slate let us leave on it all the sums that have been worked out right. Originality in design and novelty of form are not essential. The novelty of to-day is the monstrosity of to-morrow. A review of the houses of the past will show that it is not the cleverness of their designs nor the novelty and originality of their work which delights us. These qualities are more apt to constitute a weakness. Soundness and common-sense are more valuable qualities in building than cleverness. When all is said, it seems to me the best kind of house is that which possesses that depth and earnestness of appeal which belonged to the old houses of the craftsman period, and in which the mystery and magic of romance seemed the outcome of work done in simple, honest and straightforward ways. One of the most depressing qualities of modern building is the deadly soul-destroying stupidity of it all—the waste of human faculty in trying to achieve mechanical regularity, as if man with all his powers could find nothing better to emulate than the work of a machine. And so one of the most cheering features in the old craftsman work is the intelligence it displays in this respect.

I know there are those who may appreciate more the work of the scholar period with its symmetrical façades, its superficial refinements, and its coldly correct and severe apartments. Or, again, there are others who regard the whole application of artistic ideals to the house as something of a nuisance, who would have the artist keep within his proper field as a painter of pictures, and who look upon the house as a purely utilitarian affair, a kind of glorified pig's trough where meals may be conveniently eaten.

Such varied ideals must be the outcome of various minds, and I can only speak of my own dream of the house. Mere conveniences,

much as I appreciate them, would not fulfil my demands, and the strict and bounded formality of scholarly architecture leaves me cold and dissatisfied. Give me rather the house of romance. I would have as its main apartment a hall or houseplace of ample floor space, broad and low. Great oak beams should span it. and great oak boards compose its floor. At one end, a deep and wide ingle with one of those open chimneys, in which one can see the blue smoke from the wood fire swirling kind which used to be made by the old English craftsman. The house should, indeed, breathe out those happy influences which go with this home-made kind of work, without a hint of the glib and shallow dexterities of the factory or the products of modern trade art. And, above all, I would have nothing too fine or dainty for its uses, and should refuse to be intimidated by the silent tyranny of artistic furnishings. This hall must be of such a homely kind that my dog may enter there without rebuke. It must not

Fig. 18.—"The Cloisters." (The Dining Room.)

upwards, would please me better than any narrow modern grate with its petty art tiles and mantel. On the wide hearth the proper appointments of the fireside would twinkle and gleam in the firelight. And on the walls I would have no machine-made picture rails, no friezes or any paperhanger's art, only innocent spaces of white, varied perhaps with a tapestry hanging on such solid timbers as the structure of the house requires. There would be a few rugs on the oak floor, and the few furnishings would be of the easy home-made merely look like a piece of a cabinet-maker's shop window nor represent a correct reproduction of any period. Nor must it appear as a museum, with its walls and floor space crowded with a jackdaw hoard of art treasures. There should be no more furniture there than the uses of the room demand, and the quality I should most appreciate would be restfulness and quiet simplicity.

Having secured this central apartment, which would almost constitute the house, the further development of the plan would depend on

the resources at my disposal. Opening from the wide spaces of the hall would be a little "growlery" or study, like a little chapel attached to the nave of an old church, and this might well be lined with books. Its smallness would give it a distinctly intimate quality, and would never appear cramped owing to its immediate connection with the roomy hall. Opening off The woodwork here would be painted green, and the general effect would have the fresh cleanly aspect of the Dutch kitchen. I should not consider it essential to make a great feature of the staircase, and in small houses there is much to be said for the old cottage type of stairs which open from the hall by a door which appears to be a cupboard. The bedrooms

Fig. 19.—"The Cloisters." (The Sitting Room.)

the hall again would be the dining-room, and this I should like to have panelled in oak. Beyond the dining-room, the serving pantry would communicate with it by a door which would disappear as a door, and become mere panelling when shut. The kitchen premises, compactly and serviceably arranged, should as far as possible be lined with white tiles, not of the usual harsh, glaring, modern quality, but with the friendly twinkle of the Dutch tiles. would be broad and low in their proportions with long low casement windows; and, arranging the bath-room close to a dressing-room, it would be well to have an extra bath in the latter.

The conception of the house, considered from the artistic point of view, will in no way militate against more practical considerations. The absence of unnecessary furnishings will make it easy to clean, and the saving of all unnecessary labour will be to a great extent the reward of

FIG. 20.—"THE CLOISTERS." (A Dressing Room.)

a proper regard to an ideal of simplicity. I do not propose to have a white marble threshold at the entrance with a spray of water specially laid on to clean it, as Mr. Arnold Bennett has ingeniously proposed. My threshold will be of oak. Nor do I intend to round off all the corners of the rooms. But I should have, as far as possible, fixed basins in the bedrooms with hot and cold water laid on, and, above all, if funds would permit, a proper installation of a vacuum cleaning plant, so that the usual method of chasing dust from place to place in the house should be replaced by a scheme for drawing it down to a receptacle in the basement. In the house I am considering it will hardly be possible to rely entirely on the fires to warm it completely, especially in the case of the hall or houseplace, where the great open hearth and chimney is deliberately chosen in favour of the modern grate. I do not, however, wish you too hastily to dismiss the old open fire as entirely unscientific. The great mass of brickwork in which these old fireplaces were formed, centrally situated in the house, actually forms a storehouse of heat which is retained by the brickwork—for brick has the quality of absorbing and holding and gradually radiating heat, so that in baking bread in an old-fashioned brick oven, for instance, the fire is extinguished before the oven is used. And this storage of central heat in the house provides a continual supply of warmth to the adjoining rooms. If, in addition to this, a modern system of central heating is introduced, in cold weather it will be possible to use every part of the rooms, and the fire itself will mainly attract us for its beauty. To remove the open fire altogether, as in Continental houses, is from a scientific point of view quite reasonable. But I doubt whether there is anyone who is not notably warmed in spirit as well as in body by the sight of a fire on a cheerless day. A room without a fire is like a landscape without the sun. Even when cramped in the narrow confines of a modern grate, the fire asserts its charm. But when it has its ancient setting of the great open hearth, when it is composed of logs and snapping twigs, and the light of it gleams on copper and brass, it creates for us a picture we cannot well do without. It seems to be the warm heart of the

house and the symbol of its hospitalities, and few scents are more welcome than the aromatic incense of the burning wood.

In this rough sketch of an ideal house, it will be noted I have been mainly concerned with the interior, partly because it seems to me most important, and also because I believe, if the general proportions of the rooms are good, the world of Nature, and this harmony can only be achieved by proportion and workmanship of the right kind, and by that kind of design, which can hardly be called design at all, which is the resultant of internal requirements. A somewhat casual, rambling and unconscious air, as of a building which has grown out of the ground and is the outcome of local conditions, seems better than

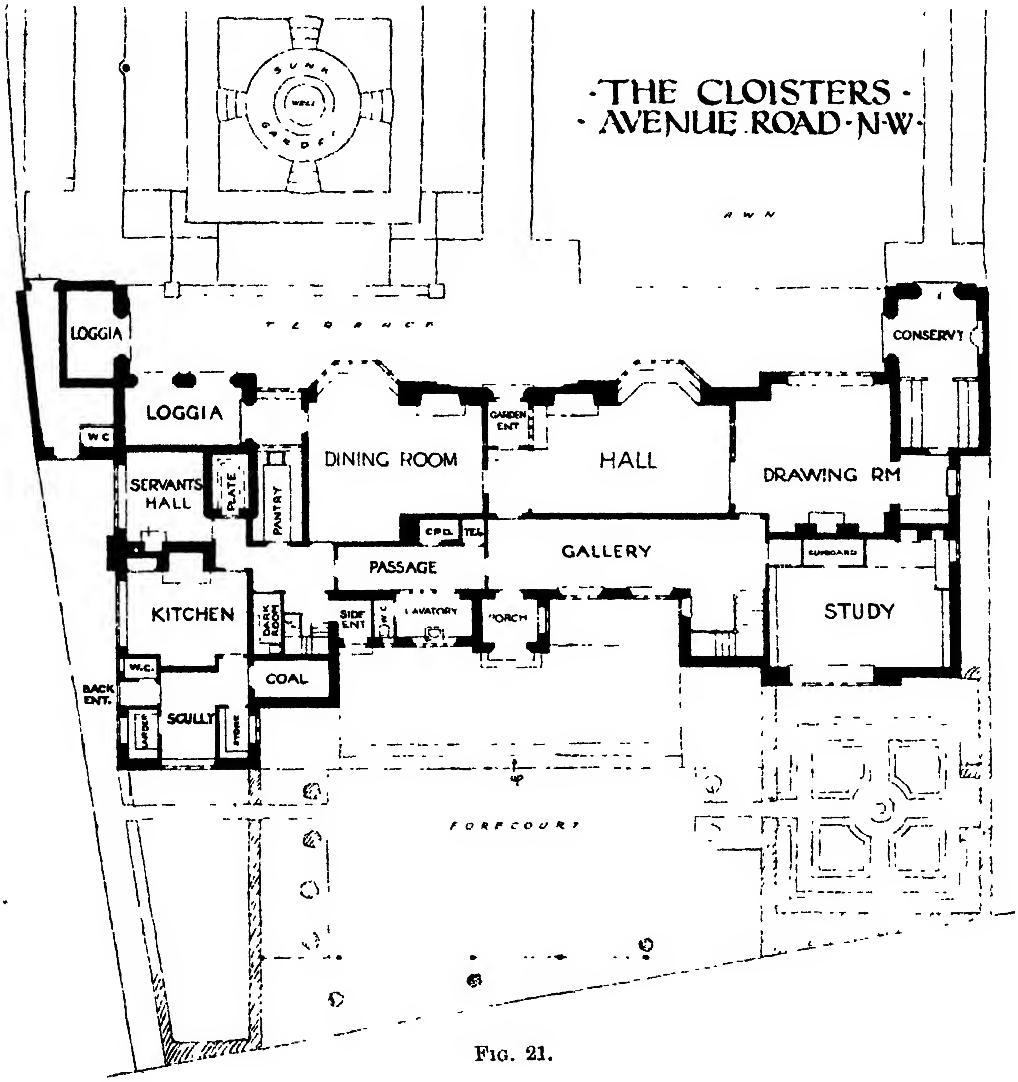

Fig. 21.

proportions of the exterior will be no less satisfactory. Houses, I think, should be designed from within outwards. And then I always prefer the kind of house which dissembles a little in its outward aspect. An imposing façade is somewhat of a bore. It seems to stare one out of countenance. For a country house especially, the best that can be said for the exterior is that it is in harmony with the some imported preconception in the latest architectural fashion of the day. And in the general tone and colouring of the building, in most cases, the natural principle of protective tints may be wisely adopted, so that the house seems almost to become a piece of Nature.

The kind of garden which should surround the house I can only briefly refer to here. I would have no vague and shapeless shrubberies

or curly paths and sinuous carriage-drive. The garden would be an outdoor extension of the house, and consist of green-walled apartments linked together to form vista lines. The paths should, as far as possible, be paved with stone or brick, and these in many cases set in mown grass, or bordered with spreading flowers which would invade their boundaries. There should be no hard clipped grass edges: the same fatal spirit of mechanical regularity which has been banished from the house should find no place in the garden. Flowers should be set in masses and drifts of colour, and not dotted at regular intervals in the borders. The horrid trinity of calceolaria, geranium, and lobelia should edge no paths of mine. It should be a garden somewhat formal and yet not without a casual air, with massed profusion of flowers relieved against dark backgrounds— a garden of sunshine and shade, with open spaces of mown grass and many roses, carnations, lilies, and other old-fashioned flowers. It should not reveal at once all its beauties. And, if possible, there should be added the pleasant chatter of running water, as well as the stillness of deep pools.

In revising these rambling remarks of mine on house building, I am painfully conscious that I have done but scant justice to my subject. The soul of the house is an elusive thing. It can hardly be described in words, and only faintly indicated in pictures or photographs. Only in the actual buildings themselves do we experience the impact of their personalities. And how varied these are! In the old craftsman houses, especially when they are unoccupied and free from modern trappings, one is aware of all kinds of deep influences and unspoken messages breathed forth from the walls. One seems to be brought into touch with those long-departed builders, and to realise here in their work the depth and earnestness of their endeavour. Something of their inmost life has been projected through the ages, and has taken definite shape in the work of their hands; and, as we pass from room to room, we find ourselves soothed and charmed and enveloped in an atmosphere of peace. The whole building seems to hold the secret of some exquisite enchantment, and active occupation for the mind does not seem necessary there, for the building itself is a continual feast. In the average modern house, with its harsh repellent personality, we must always be doing something to escape from its influence. We can only bear to live in it by continually looking out of the window at the "view." It is impossible to escape from the inherent meanness and sordidness of its nature, disguise it as we will with elaborate furnishings, and, when empty of them, it stands revealed in its true character: it is desolate indeed.

Building is not recognised at all as an art in the modern world, where the popular conception of art is of something which is framed and glazed and put in a public gallery; and until we begin to learn that art is something more than that, we cannot hope to have any good building again, or anything better than what Professor Lethaby has aptly called "architect's architecture" for the few, and what I may call "builder's building" for the many.

HINDU PIECE-GOODS TICKETS.

According to the *Pioneer Mail*, the Marwari Chamber of Commerce in Calcutta have recently applied to the Bengal Chamber of Commerce to use its influence to "abolish the use of pictorial representations of Hindu gods and goddesses as designs for stamps, tickets, and labels on boxes, packages, and pieces of various kinds of goods and articles of merchandise," and so on. It would be interesting to discover the genesis of the request. These tickets of "gods and goddesses," their incarnations, their satellites, and of incidents of Hindu mythology, were all introduced by the bania dealers, a large proportion of whom, all over up-country and in Calcutta, are Marwaris. All these pictures of Krishna and Bhairo and Devi and Kali, it is true, are printed in Manchester, but they were prepared from hand-paintings by Hindu Massawars and sent home through importing houses by the wholesale dealers of buyers of cloth. In the up-country markets and in Calcutta there is probably not a single Mohammedan wholesale importer (known as a "dealer") of cotton piece-goods; these dealers are all Hindus. It is the Hindu dealer who has himself selected practically every Hindu "god" ticket now appearing on every quality of cotton piece-goods imported into India. The Marwari Chamber "notices with regret" that the practice "necessarily leads to pictures of the gods and goddesses whose images form the subjects of worship in Hindu homes and temples being thrown away in the street, trampled under foot, etc., etc., which cannot but hurt the religious feelings of the Hindus." The average Manchester or Glasgow piece-goods' expert certainly cannot distinguish one god of the Hindu pantheon from another, and the responsibility for selecting Hindu tickets is on the Marwari dealer. The suggestion that the use of Hindu gods' and goddesses' tickets has been at the instigation of or encouraged in any way by European houses is preposterous, and is so absurdly ingenuous that it certainly merits further investigation. Does the Marwari pretend he is suddenly going to give up tickets, the abandonment of which

means further losses in an already depreciated piece-goods market, and an extraordinary dislocation of trade? There are thousands of cases—*i.e.*, packages and bales—which mean millions of yards of certain Manchester goods, which sell in every village bazaar in Northern India, to take one concrete instance, under the name of a certain popular Hindu deity. This is a proprietary mark which has been imported for twenty or thirty years past. Many Indian dealers import this one mark and nothing else. The villager refuses to buy or accept any other mark. How are the dozens of established Hindu deity marks to be substituted? There are hundreds of similar instances—white shirtings, mulls, dhotics, red and dyed goods, prints, all with well-known marks or tickets (or "chops" as they are called further East), all with representations of Hindu gods and goddesses. Practically every bania's shop in India has hundreds of these "piece-goods" tickets pasted on the back of his shop walls, doors, windows, etc. They are beautiful pictures to him of his particular deities or incarnations thereof, and he appreciates them. A dislocation of established marks and tickets on piece-goods at the present juncture is most undesirable. The piece-goods market is bad enough as it is—there are other competitors in the field, and when the war is over it will probably be difficult enough for piece-goods importers to hold their own against "other and certain" new competitors. But to prepare the way for this outside anticipated competition by breaking up established and proprietary marks just at the very moment when we all would like to see them established firmer than ever, would be a policy of suicide which one does not ordinarily associate with the outlook of the Marwari. The whole matter is far more serious than it may appear to the casual observer and to the ordinary official up-country, but it merits notice as it affects one of the most important trades of the country. It should be realised that on an average about 40 per cent. of the total of imports into India consists of cotton piece-goods.

ENGINEERING NOTES.

The Longest Simple Truss Span in the World.—Silicon-steel main members and nickel steel eye-bars have been adopted for the main truss spans of the new bridge to be constructed over the Ohio River at Metropolitis, Illinois. This structure will contain the longest simple truss span in the world—about 720 ft. centre to centre of the end pins. The total length of the steelwork will be more than one mile, and the total cost is estimated at about £700,000. The bridge is to be a double-track structure, designed for unusually heavy live loading. The total length of the steelwork in the new structure will be about 5,487 ft., consisting of six through-spans and one deck-truss span, and a viaduct approach on each side, in which fifteen 80-ft. towers, supporting girders of various lengths from 62 ft. to 90 ft. 6 in., will be used. The floor of these approaches will be of the solid ballasted type, constructed on 0·2 and 0·3 per cent. grades, while the main truss floors are of the usual open deck construction. The underclearance required above high water is 53 ft., with 700 ft. maximum clear opening. All the trusses, except those in the shorter spans at each end, are of the through curved-chord pin-connected type, with sub-panels throughout, using sub-diagonals in compression. The piers are being constructed by the use of pneumatic caissons, which vary in size from 47 ft. by 80 ft. to 60 ft. by 110 ft. The fixed and expansion ends alternate, the Illinois end of each span being fixed. Piles are used under the concrete piers on the approaches.

Water Power in Norway.—The exploitation of the Saude Falls, according to the *Times*, is now to be taken in hand. From the Storli River a tunnel, 600 metres in length will be blasted in the rock, and the height of fall available will be no less than 280 metres. The power station here, the first of a series, will have a capacity of 27,000 h.p. By damming the level of the Storli, water will be raised 12 metres, and that of the Dalwater 20 metres. The level of several other lakes, or waters as they are generally called, will be raised by means of dams. The next station will be placed at the Dalwater, and will have a capacity of 10,000 to 12,000 h.p.; somewhat lower, a third station, the largest of them all, with a calculated capacity of 40,000 to 45,000 h.p., will be established; and the fourth, and last, of 10,000 to 12,000 h.p., will be constructed at Slettedal. The aggregate power obtained from the exploitation of this cluster of falls will amount to 100,000 h.p., and 40,000 h.p. have already been disposed of to the Electric Furnace Products Co., which may want an additional like quantity. The delivery is to be by degrees, the first 20,000 h.p. being available at the beginning of 1918. The first phase of construction, 40,000 h.p., is calculated to entail an expenditure of from £350,000 to £400,000; the next, 40,000 h.p., will be somewhat more expensive. While the work at the Saude Falls is only just being started, an important section of another kindred, and still larger, undertaking, has been completed, viz., the huge dam of the Vamma hydro-electric power station, which forms a reservoir holding 20,000,000 cubic metres. It has been built for the purpose of raising the level of the Glommen, and thereby increasing the height of the fall. When the installation is complete, there will be some 180,000 h.p. available. The portion of the power station now built is to contain six units, of which two, each of 12,000 h.p., are being installed.

The Leon Torpedo.—In a recent issue of *Le Génie Civil* the sinking of the warships "Bouvet," "Irresistible," and "Ocean" in the Dardanelles is attributed to the Leon torpedo. This weapon was invented in 1907 by a Swedish officer, Captain Carl Leon, and combines the characteristics of the

submarine mine and the self-propelled torpedo. Its activities consist in drifting with the tide and predetermined vertical movements produced by its own motive power. For instance, the torpedo may be required to drift about at a certain depth. The pressure of the water, varying according to the depth, actuates a sensitive hydrostat, which closes or opens a switch connecting a battery with an electric motor, which drives a vertical propeller, keeping the torpedo within a certain depth. For sinking ships in an enemy harbour, these torpedoes may be sent to drift in with the ingoing tide, a clock mechanism bringing the motive power into operation at the turn of the tide, making the torpedoes sink and rise again at the ebb. As originally constructed, the motive power was provided by compressed air which, suitably controlled by a hydrostat, allowed the air to be admitted to, or escape from, a flotation chamber, which thus governed the buoyancy and maintained the torpedo at the predetermined level. As now constructed, however, the movements are produced by a vertical propeller and electric motor located at the lower end of the torpedo body. The battery is contained in a central compartment, while the explosive and firing apparatus is placed in the upper end, the weights as a whole being arranged so that when submerged the machine takes up a vertical position. A "stabilising" mechanism is also provided, whereby the buoyancy of the torpedo can be adjusted to suit the density of the water.

Special Steel for Rails.—Mr. W. C. Cushing, permanent way engineer of the Pennsylvania railways, in the July *Bulletin* of the American Railway Engineering Association, summarises his views as follows: (1) Cast manganese steel has been proved by long experience, under exacting conditions, to be a satisfactory and safe metal for the manufacture of points and crossings. (2) The trials of rolled manganese steel for rails and for the manufacture of points and crossings have not been so extensive as with the cast product, but have been continued to a sufficient degree to enable us to conclude that it will be ultimately suitable for these uses at locations where great strength, toughness and a maximum abrasive resistance are desirable. (3) The experiments with nickel, and nickel and chromium in certain proportions, in rail steel have not, up to the present time, been entirely satisfactory; but the accepted employment of nickel steel in bridge construction, and the trials of nickel and chromium in other proportions in rail steel, especially when incorporated as two of the natural elements of the iron ore, justify continued use. (4) The use of high carbon (over 80 per cent.) in rails weighing 85 lb. per yard, in combination with ·92 to 1·00 per cent. of nickel, and ·24 to ·29 per cent. of chromium, has not been satisfactory. The conditions with rail sections of greater weight might be entirely different. (5) Further study of the qualities possessed by high silicon rails, that is, steel with over ·3 per cent. of silicon, is advisable. (6) The value of the use of ferro-titanium in rail steel manufacture as a "physic" for improving the condition of solidity of the metal is conceded, but at the same time steps should be taken to overcome its injurious effect in deepening the "pipe" in the ingot. (7) Heat-treated rails, and those manufactured with the assistance of the electric process, are at present in experimental use only, but the possibility of future value is promising, and the study should be continued. Mr. Cushing's paper was to have been presented at the International Railway Congress in Berlin, but was transferred to the above association owing to the war.

The Coming of the Motor Plough.—Of all the work which has to be done on farms, ploughing is perhaps the most extravagant in power and the most dependent upon the conditions of the land and weather. On large estates the cable system of steam ploughing has been brought to a high state of perfection. Not many farmers, however, can afford a set of steam-ploughing tackle, nor are there many farms in these islands of such a size as would make its employment a paying proposition. As the *Engineer* points out, what is greatly wanted is a motor tractor neither too costly nor too complicated—that can be put to some practical use at all seasons of the year, and it would appear that such a machine is now in course of evolution. Apart from the cable-haulage system of ploughing already mentioned, the systems of motor ploughing are chiefly divided into two classes, namely, those in which the motive mechanism and the plough are two separate units and those in which the two are combined. For all-round usefulness the separate haulage system possesses important advantages, as motive mechanism can be readily attached to various kinds of implements. The disadvantages urged against the separate tractor are several. One is the necessity for employing two men—one on the tractor and one on the plough. With regard to the type of motor to be used, the steam-engine has not yet been adapted to the self-contained machine, owing to the weight of the water and fuel which it has to carry. So far the petrol engine has monopolised the field, and with spirit at a moderate price such engines will continue in favour, though developments may be expected in connection with paraffin engines. As regards the amount of power required, current practice would seem to show that with engines of 20 to 25 h.p. satisfactory work can be done on average land with ploughs of two and even three furrows and taking cuts 7 in. deep. With this amount of power it is possible to plough from three to six acres in a day of nine hours. In order to relieve the land from excessive pressure and give a more direct pull when engaged in pulling the plough, some tractors are designed to run with one driving wheel in the furrow. This method has also the advantage of keeping the furrows parallel and making steering easy. As several of the

leading manufacturers of motor ploughs have adopted this idea it would seem that the system is based on sound principles. The petrol consumed by a motor plough is said to be about two gallons per acre of land ploughed and its capacity three acres per day of nine hours.

OBITUARY.

SIR ROBERT LAIDLAW.—Sir Robert Laidlaw died on the 3rd inst. at his residence, Warren House, Hayes, Kent. He was born at Bonchester, Roxburghshire, in 1856. Going out to India, he founded the well-known firm of Whiteaway, Laidlaw & Co., of which he was chairman, as well as of the Dusun Durian Rubber Estate, Limited. He was also largely interested in other enterprises in the East: he owned tea estates in Darjeeling, and had considerable holdings in rubber estates in the Federated Malay States and Java. In 1909 he was the British representative at the International Opium Commission at Shanghai, and in recognition of his services there he was created a knight.

From 1906 to 1910 he sat as Liberal M.P. for East Renfrewshire, and four years ago he was adopted as prospective Liberal candidate for his native county, Roxburghshire. He was keenly interested in Indian problems, especially those connected with education. He took a prominent part in the recent movement to provide educational facilities for poor children of British descent in India, for which £100,000 was raised in this country. He also gave much time and energy to Y.M.C.A. and missionary work. He was treasurer of the London Missionary Society, and had been President of the World's Sunday School Union.

He was elected a member of the Royal Society of Arts in 1903.

GENERAL NOTES.

THE COAL-TAR DYE INDUSTRY.—The October number of *Science Progress* contains the first part of an article on "The Influence of Research on the Development of the Coal-Tar Dye Industry," by Dr. F. A. Mason. An interesting account is given of the origin of the industry in this country, and especially of the parts played by Perkin, Hofmann, and Caro. Dr. Mason makes it clear that the reason why the industry, although it was started, and for a time made considerable and promising progress in this country, subsequently became the monopoly of Germany, was the dearth of British students of organic chemistry. "Both by nature and good fortune," he writes, "England seemed to be destined to be the great coal-tar dye producing country of the world; Great Britain produced more tar than any other country, the first synthetic dye was discovered here, and Professor Hofmann himself, at the Royal College of Chemistry, was the centre of attraction of the industry, one thing only was lacking, namely, a sufficient scientific education of the general public, such as was already obtaining in Germany, and a sympathetic understanding and appreciation of the methods and objects of research. To this last is to be traced, directly and indirectly, the ultimate collapse of the British dye industry."

A MAHARANEE'S WAR JOURNAL.—A weekly journal has been started by Her Highness the Maharanee of Bhavnagar for the special purpose of encouraging recruiting in India, and giving the people there an accurate account of the operations week by week. German agencies had been very busy at first in propagating in India, as elsewhere, falsehoods about the causes of the war, and this journal, called "British and Hindi Vikram," in its first numbers successfully dispelled such misrepresentations. It has continued to chronicle the events of the war from official and authoritative sources, occasionally accompanied with illustrations, and has thus been the means of diffusing among the vast Gujarati population of India, who are not able to read English papers, accurate information regarding the achievements of British and Indian arms. It is, we believe, the first instance of journalistic enterprise on the part of an Indian princess, and a notable item in the scheme of loyal co-operation which her husband, the Maharaja of Bhavnagar, has been rendering in various ways to the paramount Power from the first day of the war.

COMMERCIAL MUSEUM IN CALCUTTA.—A press *communiqué* states that, in view of the success which attended the sample exhibition of goods imported from Germany and Austria-Hungary and of competing Indian manufacturers recently held at Calcutta and certain other commercial centres, the Government of India have decided to establish a permanent commercial museum in India. The museum will be located in Calcutta, and will be attached to and form part of the Department of Commercial Intelligence. The collection of samples and exhibits will naturally take time, and the development of the museum must necessarily be gradual. It is intended that the museum should contain samples of the principal manufactures imported into India from all foreign countries with which there is any existing or prospective Indian competition, and also representative samples of the corresponding Indian manufactures. It will also contain samples of goods marketed in foreign countries which India might be in a position to supply. It is further intended to exhibit representative samples of raw materials exported to foreign countries to be reimported which occur in India, but are not at present worked, although products manufactured from similar materials are imported in considerable quantities. The samples exhibited will be supplemented by catalogues and price lists, which will be kept continuously up-to-date by printed statistics, wherever possible,

showing the extent of the various markets in India and abroad, and by other information explanatory of the details of the trade names and addresses of firms dealing in the various trades will be maintained in the Commercial Intelligence Department, and will be available for the information of buyers and sellers.

CASCARA SAGRADA.—An account of the history, growth, methods of collection, and bibliography of the drug Cascara Sagrada (*Rhamnus Purshiana*) is contained in a recent issue of the *American Journal of Pharmacy*. The tree is stated to occur in the States of Washington, Oregon and Northern California, and in the Cascade mountains of British Columbia. It is said to prefer a light sandy soil, with a good rainfall, and grows at altitudes varying from sea-level to 2,000 ft. The tree grows fairly rapidly, reaching a height of 20 ft. to 30 ft. and a diameter of 6 in. to 8 in. in about ten years. Trees of over 4 in. diameter are felled, the bark stripped during the summer months and cured by a few days' exposure to sunlight. During the period 1902-1912 the annual average production is stated to have been about 600 tons.

PRESERVED MANGOES. — A new industry, the preservation of mangoes, has recently been started in Manila. Although the enterprise is at present on a small scale, it promises to develop to very considerable proportions. The Philippines is the home of the mango, and for years efforts have been made to prolong the use of the fruit and its excellent flavour, the season for the mango being comparatively short, and the delicate nature of the fruit preventing its retention for any length of time, or its export from the islands. It is stated that a satisfactory process of preserving the fruit in glass jars has been discovered. The preserved fruit is to be known as mango honey.

THE EXPORT OF CACAO FROM ECUADOR.—The yield of the cacao harvest in the Republic of Ecuador last year appears to have been below the average. The exports for the six months ending January 31st last, which amounted to 168,087 sacks, show a falling off of 132,625 sacks, as compared with those of the corresponding period of the previous year, which were 300,772 sacks. The average weight of the sack is 150 lb. net. The exports from Guayaquil, the chief port, represent about four-fifths of the entire crop, and about three-fifths of its total value. The exports to Italy, which in 1913 only amounted to 2,600 sacks, increased last year to 15,763 sacks, weighing 1,075,760 kilogrammes (2,372,050 lb.), to the value of 1,000,000 Italian lire (£44,000 sterling) f.o.b. Guayaquil.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 15...Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. J. W. Brushwood, "Printing, Masking, and Toning Cyko Paper."

Geographical Society, Burlington-gardens, W., 8.30 p.m. The President, "The Southern Frontier of Austria."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Mr. S. N. Singh, "Indian India and its Rajas."

TUESDAY, NOVEMBER 16...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mr. P. S. Florence, "The Human Limits to Production."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Messrs. R. T. Glazebrook, W. F. Higgins, and J. R. Pannell, "The Viscosity of Oil in Relation to the Rate of Flow through Pipes."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Sir John Benton, "The Punjab Triple Canal System."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Dr. O. Tugman, "The Resolving Power of Photographic Plates."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Professor H. J. Fleure and Dr. T. C. James, "The Welsh People: an Anthropological Analysis."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. R. L. N. Michell, "Cyprus To-day."

WEDNESDAY, NOVEMBER 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Opening Address of the 162nd Session by Dr. Dugald Clerk, "English and German Methods Contrasted."

Meteorological Society, 70, Victoria-street, S.W., 7.30 p.m. 1. Mr. J. S. Dines, "The Mounting and Illumination of Barometers and the Accuracy obtainable in the Readings." 2. Mr. N. A. Comissopulos, "On the Seasonal Variability of Rainfall over the British Isles."

Geological Society, Burlington House, W., 8 p.m.

Microscopical Society, 20, Hanover-square, W., 8 p.m. Messrs. E. Heron-Allen and A. Earland, "The Foraminifera of the Shore Sands and Shallow Water Zone of the South Coast of Cornwall."

Entomological Society, 11, Chandos-street, W., 8 p.m.

Chadwick Public Lecture, at the Royal Sanitary Institute, 90, Buckingham Palace road, S.W., 8.15 p.m. Mr. W. E. Riley, "Some Conclusions on Housing our Workers."

THURSDAY, NOVEMBER 18...Geographical Society, Kensington Gore, S.W., 5 p.m. Mr. C. Wallis, "Distribution of Nationalities in Hungary."

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. W. M. Webb, "Hollow-shafted Feathers." 2. Dr. E. J. Salisbury, "Photographic Studies of Welsh Vegetation."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace road, S.W., 6 p.m. Dr. P. B. Ballard, "Standards of Proficiency in Reading."

Chemical Society, Burlington House, W., 8.30 p.m. Dr. E. W. Russell, "The Principles of Crop Production."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. S. Rowntree, "How the Elephant got his Trunk."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Presidential Address by Mr. C. P. Sparks.

Historical Society, 22, Russell-square, W.C., 5 p.m. Mrs. H. Jenkinson, "A Forgotten Princess (Joan, daughter of Edward III.)."

FRIDAY, NOVEMBER 19...Dante Society, 38, Conduit-street, W., 3 p.m. Extraordinary Meeting.

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 8 p.m. 1. Professors J. O. Arnold and A. A. Read, "The Chemical and Mechanical Relations of Iron, Molybdenum, and Carbon." 2. Dr. J. O. Arnold, "The Cause and Effect of 'Ghost Lines' in Large Steel Forgings."

CONTRIBUTIONS TO THE READING-ROOM.

The Council have to acknowledge, with thanks to the Proprietors, the receipt of the following Transactions of Societies and other Periodicals.

INDEX TO VOL. LXIII.

A.

Abney, Sir William de W., K.C.B., D.C.L., D.Sc., F.R.S., *paper*, testing pigments for permanence of colour, 85
Abyssinia and its trade, 481
Ackermann, A. S. E., B.Sc.(Eng.), A.M.Inst.C.E., *paper*, the utilisation of solar energy, 538; silver medal awarded to, for his paper, 742
Acorns, horse chestnuts, and beech mast, food value of, 19
Aeroplane construction in Australia, 922
——— engineering, 922
Aeroplaning progress in 1914, 345
Afghanistan, agricultural and mineral resources of, 440
Agricultural co-operation in South Australia, 581
Agriculture, Indian, 783
——— in Bengal, 763
——— — England, 699
——— United Kingdom, 924
———, tropical (proceedings of international congress), 258
Aircraft for Italian army, 234
Akabah, capture of, 59
Albert medal, list of awards, 353; presentation to Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., 489; awarded to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S., 613; annual report, 741
ALDRED LECTURE – L'évolution de l'école Belge de peinture (1830–1900), Paul Lambotte, 469; annual report, 741
Aluminium, 42
Alundum (non-porous) for protecting sheaths of pyrometers, *letter*, Chas. R. Darling, 946
Alward, G. L., *disc.*, the state and the fisherman, 528
Amber industry, German, 852
American mails, 589
Angora goat, 99
Aqueduct in Apulia, 820
Architecture: house building, past and present, *Cantor Lectures* by M. H. Baillie Scott, 989, 1004, 1019, *syllabus*, 351
Armstrong, Sir Charles H., *paper*, Indian trade and the war, 645; silver medal awarded to, for his paper, 742
Armstrong, Professor H. E., the future of indigo, 149
Army clothing, 443
———, the Indian, *paper* by Lieut.-Colonel A. C. Yate, I.A. (retired), 449
Art schools, 933
——— work, annual of, 154
Artesian well, water power from, 80
Arts and crafts, 22, 96, 165, 256, 379, 482, 582, 680, 751, 816, 878, 933, 983
——— at British industries fair, 681
——— (British) at Paris, 165
Asbestos in Tasmania, 700
Ash (volcanic) on the great plains of North America, by Chas. N. Gould, Ph.D., 94
Ashley, Professor W. J., M.A., M.Com., Ph.D., *paper*, the economic position of Germany, 303; silver medal awarded to, for his paper, 742
Asphalt in the State of Oklahoma, by Chas. N. Gould, Ph.D., 132
Atkinson, L. B., *disc.*, measurement of the efficiency of domestic fires, 577
Australia, gold production in, 115
———, northern territory of, *paper* by David Lindsay, 386
———, transcontinental railways of, 114
Australian manufacturers, bounties to, 115
——— rainfall, 423
Automobile parts, shortage of, 62

B.

Baker, T. Thorne, *paper*, industrial uses of radium, 490
Banana flour, 958
Bancroft, Sir Squire, *chair*, Shakespeare's profession, 325
Bank dividends, 170
——— gold reserves, 234
Barker, A. H., *disc.*, measurement of efficiency of domestic fires, 579
Barnes, Sir Hugh S., K.C.S.I., K.C.V.O., *disc.*, Basra and the Shatt-ul-Arab, 517
Barry, James, R.A., "Adam and Eve" presented to the National Gallery of Ireland, 569; annual report, 746
Basket-making, Philippine progress in, 163
Baskets used by German artillery, 21
Basra and the Shatt-ul-Arab, *paper* by Perceval Landon, 505
Bayley, Sir Steuart Colvin, G.C.S.I., C.I.E., *chair*, the Indian indigo industry, 117; *disc.*, tribes of the Brahmaputra valley, 301; *disc.*, the Indian army, 461; annual meeting, 749
Baynes, Alfred Henry, *obituary*, 81
Beadle, Clayton, *disc.*, the empire's resources in paper-making materials, 634
Beale, Octavius Charles, *paper*, expansion of British industry after the war, 221
Beardshaw, William F., *disc.*, recent progress in pyrometry, 607
Bêche-de-mer industry in Bahamas, 426
Beds (metal) in Brazil, 155
Beech mast, acorns, and horse chestnuts, food value of, 19
Beeswax, African wild, 234
Beet (sugar) culture, 138
Belge (comité) pour le commerce avec les alliés, 286
———, l'évolution de l'école, de peinture (1830–1900), *Aldred Lecture* by Paul Lambotte, 469
Belges, Constantin Meunier et les sculpteurs, *Special Lecture* by Paul Lambotte, 669
Belgian intensive culture, 135
——— soldiers comforts fund, 772
——— work at Hammersmith, 755
Belgians, H.M. the King of, Honorary Royal Fellow, 537
Belgium, a short holiday in, by T. B. Grierson, M.Inst.C.E., 805
——— the work of the war refugees' committee, *paper* by Lady Lugard, 429
Benares, industries of, 344
Bengal industries, 690
Bengasi, trade and commerce of, 1913, 944
Bennett, T. J., C.I.E., *disc.*, Indian trade and the war, 661
Berry, A. E., *disc.*, the supply of chemicals to Britain and her dependencies, 34
Besant, Arthur Digby, B.A., F.I.A., Canadian indebtedness, 337
Bhownaggree, Sir Mancherjee M., K.C.I.E., *disc.*, Nepal, 247
Bird sanctuary, Brent valley, 138
Birds, value of, to man, by James Buckland, 701; *letters*, Frank Cundall, 867; J. Buckland, 999
Birmingham power-plant, 346
Biscuits, army, 804
"Bishop Blaize" inns, 871
Bomb calorimeters, standardisation of, 890

Books, Notes on :—
Amphlett, George Thomas, History of the Standard Bank of South Africa, 445
Balls, W. Lawrence, M.A., the Development and Properties of Raw Cotton, 923
Beaumont, Roberts, M.Sc., M.I.Mech.E., Woollen and Worsted, 586
Berry, Henry F., A History of the Royal Dublin Society, 585
Birdwood, Sir George, K.C.I.E., Sva, 349
Bone, Philip J., The Guitar and Mandoline, 41
Calvert, Albert F., Salt in Cheshire, 935
Cressy, Edward, Discoveries and Inventions of the Twentieth Century, 835
Crew, Albert, The Conduct of and Procedure at Public and Company Meetings, 233
Darling, Charles R., Liquid Drops and Globules, 138
Dearle, N. B., Industrial Training, 698
De Villamil, Lieut.-Colonel R., R.E. (retired), Motion of Liquids, 446
Ficke, Arthur Davison, Chats on Japanese Prints, 731
Gage, Professor Simon Henry and Henry Phelps Gage, Optic Projection, 205
Gardner, Walter M., M.Sc., The British Coal-Tar Industry, 986
Gaster, Leon, and J. S. Dow, Modern Illuminants and Illuminating Engineering, 803
Hardy, G. Hurlstone, The Book of the Fly, 698
Holloway, Thomas, Levelling and its General Applications, 819
Humberstone, Thomas Lloyd, An Experiment in Industrial Research, 985
Indian Year Book, 1915, 535
Knox, G. D., The Spirit of the Soil, 984
Knox, Gordon D., Engineering, 715
Leong, Y. K., LL.B., B.Sc.(Econ.), and L. K. Tao, B.Sc.(Econ.), Village and Town Life in China, 642
Levick, Staff-Surgeon G. Murray, R.N., Natural History of the Adélie Penguin, 729
Marshall, Alfred W., M.I.Mech.E., and George Gentry, Micrometers, Slide Gauges, and Calipers, 699
Martin, Edward A., Dew-ponds, 501
Maxwell, J. F., Celtic Scribe Work, 41
Peddie, J. Taylor, F.S.S., First Principles of Production, 485

Perris, G. H., Industrial History of Modern England, 233
Phillips' Paper Trade Directory of the World, 1914-15, 923
"Phœnix," The Motor Cyclist's Handbook, 502
Photographic Almanac, British Journal, 1915, 234
Pulbrook, Ernest, The English Countryside, 715
Richardson, S. S., B.Sc., A.R.C.Sc., Magnetism and Electricity, 138
Rivington's Notes on Building Construction, 935
Scott-Mitchell, Frederick, Practical Gilding, Bronzing, Lacquering, and Glass Embossing, 803
Skrimshire, Samuel, F.S.I., Valuations, 643
Todd, John A., B.L., The World's Cotton Crops, 819
Travis, Charles, Railway Rates and Traffic, 154
Victoria and Albert Museum: Review of the Principal Acquisitions, 1914, 731
Victoria and Albert Museum :—(1) Catalogue of the Schreiber Collection of English Porcelain; (2) Guide to the Catalogue of Carpets; (3) Catalogue of a Collection of Miniatures in Plumbago, etc.; (4) Tapestries, 957
Vizetelly, Frank H., Litt.D., LL.D., Essentials of English Speech and Literature, 502
Wireless Telegraphy and Telephony, Year-Book of, 1915, 699
Wireless Time Signals, 936

Books for British civilian prisoners of war in Germany, 867
Boys, Charles Vernon, F.R.S., *chair*, the utilisation of solar energy, 637
Bracken as litter, 982
Brahmaputra valley, tribes of the, *paper* by Captain Sir George Duff Dunbar, Bt., I.A., 290
Brassey, Earl, G.C.B., *disc.*, Indian trade and the war, 661
Bray, Henry F., *letter*, Indian indigo industry, 466
Brenan, Byron, C.M.G., *disc.*, sugar and the war, 270
Bridge building in America, artistic, 973
British Association, 883
British East Africa and Uganda, the economic development of, *paper* by Major E. H. M. Leggett, R.E., D.S.O., 209; *letter*, H. B. Taylor, M.Inst.C.E., 257
British East Africa produce, 724
——— industries fair, 680
——— industry after the war, expansion of, *paper* by Octavius Charles Beale, 221
Broadbent, D. R., *letter*, utilisation of solar energy, 585
Bromley, H.A., *letter*, the empire's resources in paper-making materials, 636
Brooks, F. Vincent, *paper*, British lithography in 1915, 248
Brooms, Italian piuma-grass, 782
Bryce, Right Hon. Viscount, O.M., D.C.L., LL.D., F.R.S., *chair*, the Indian army, 449
Buchanan, George C., C.I.E., M.Inst.C.E., presentation to, of medal for his paper on the port and city of Rangoon, 17
Buckland, James, the value of birds to man, 701; *letter*, do., 999
Budget changes and textile industries, 956
Buffer stops: a frictional device, 666
Building (house), past and present, *Cantor Lectures* by M. H. Baillie Scott, 989, 1004, 1019; *syllabus*, 351
Bunder Abbas and its trade, 607
Burlton, C. H. B., *letter*, Indian trade and the war, 682
Burton, T. R., *disc.*, testing pigments for permanence of colour, 93
Busrah, British in, 134
Buxton, Sir Thomas Fowell, Bt., G.C.M.G., *obituary*, 1015

Cacao (export of) from Ecuador, 1034
——— in the Dominican republic, 784
Calendar for 1914-15, 5
Canada, hydrographic work in, 499
———, military engineering in, 466
———, trade outlook and the war, 114
———, war equipment from, 422
Canadian and British trade, 498
——— indebtedness, by Arthur Digby Besant, B.A., F.I.A., 337
——— industrial and labour conditions, 423
Canal haulage, electric, 152
——— (Panama) defences, 666
———, from an Italian point of view, 480
——— traffic, 79, 99
———, Suez, 81
——— in war time, 644
Cantor Lectures :—*Notices* of publication of reprints, 237, 947, 989; annual report, 740
1st Course:—"The history and practice of the art of printing," by R. A. Peddie, 101, 129, 142, 158; *syllabus*, 2
2nd Course:—"Oils, their production and manufacture," by F. Mollwo Perkin, Ph.D., F.I.C., F.C.S., M.Inst.P.T., 837, 853, 869; *syllabus*, 156
3rd Course:—"House building: past and present," by M. H. Baillie Scott, 989, 1004, 1019; *syllabus*, 351
4th Course:—"Foodstuffs," by David Sommerville, B.A., M.Sc., M.D., 893, 909, 925, 937
Cascara sagrada, 1034
Cassal, Colonel Charles E., *disc.*, the supply of chemicals to Britain and her dependencies, 36
Catalogues, exhibition of German trade, 716
Cedar, British Columbia red, 382
Cement in Queensland, 803
——— the Canary Islands, market for, 24
——— manufacture in India, 666
——— protected steel construction, 801
——— trade in Brazil, 441
Chadwick Lectures, 946

Chadwin, W. T., *disc.*, sugar and the war, 269
Chapman, A. Chaston, *disc.*, the supply of chemicals to Britain and her dependencies, 35
Charities, "Quarterly Review" and British, 111
Chemical trade, Britain and Germany in relation to the: *paper* by William Reginald Ormandy, D.Sc., F.C.S., 47; *letter*, R. Le Neve Foster, 167
Chemicals, supply of, to Britain and her dependencies, *paper* by Sir William A. Tilden, D.Sc., LL.D., F.R.S., 26
Chemists (industrial), training of, *letters*, W. J. Dibdin, 81; Chas. R. Darling, 98
Chengtu district, resources of, 782
China, canals of, 1016
—— electric machinery in, 852
——, engineering openings in, 903
—— (Kaihsian district), resources of, 954
——, railway and industrial schemes in, 636
—— (South), coal fields in, 981
——, Yunnan province, trade prospects in, 904
Chinese market for machinery, 567
—— native trades in Shensi, 150
Chisholm, Robert Fellowes, F.R.I.B.A., *obituary*, 697
Choco intendency, development of, 202
Chrimes, Charles Edward, *obituary*, 154
Christison, G. W., *disc.*, Nepal, 246
Christmas and the artistic crafts, 97
Cider, concentrated apple, in America, 464
Clerk, Dugald, D.Sc., F.R.S., *chair*, patent law reform, 356; elected chairman of council, 789
Clothing, economy in, 906
Cloths and skirts, 445
Coal distillation, products of, 813
—— in China, 880, 981
—— Germany, output of, 287
—— Sweden, 892
—— the United Kingdom, 1914, 732
—— industry, Japan, 82
—— measures of Queensland, 285
—— tar dye industry, 1033
—— (world's) in 1912, 286
Cocoa-bean coating in Trinidad, 317
Coconut cake as cattle food, 684
—— industry, 726
—— -water as rubber coagulant, 259
Coffee supply, far eastern, 908
Cole, Alan S., C.B., *letters*, map-making and tapestries, 40; decorative textile industries and designer's relation thereto, 282
Colebrook, Frank, *disc.*, British lithography in 1915, 253
College, Chinese conservancy engineering, 535
"Collegium," 186
Collier, the Hon. John, *paper*, portrait painting: the technique of the great masters, 189; silver medal awarded to, for his paper, 742

COLONIAL SECTION:—Annual report, 739; list of committee, 909
1st Meeting:—"The economic development of British East Africa and Uganda," by Major E. H. M. Leggett, R.E., D.S.O., 209
2nd Meeting:—"Sugar and the War," by Edward R. Davson, 261
3rd Meeting:—"The Northern Territory of Australia," by David Lindsay, 386
4th Meeting:—"The empire's resources in paper-making materials," by S. Chas. Phillips, M.S.C.I., 613

Colour, testing pigments for permanence of, *paper* by Sir William de W. Abney, K.C.B., D.C.L., D.Sc., F.R.S., 85
Colour-schemes, spring, 583
Conciliation courts in France, 38
Concrete arch, flat long-span, 866
—— in waterworks construction, 566
Concreting, electric car heaters for cold weather, 975
Contracts, government, 61
Cooking of hams, etc., in tins, 800
Copley, John, *disc.*, British lithography in 1915, 252
Copper for shells, Canadian, 976
Copra, Philippine, 697
Cork dust in Spanish fruit packing, use of, 382
Corn, new method of growing, 820
Corrosion of condenser tubes, 666
Corrugation, rail, 866
Cotton accoutrements, 61
—— as contraband, 851
—— crop in Russia, 876
—— cultivation in Uganda, 17
—— explosives, 786
—— fibre, coloured, 955
—— (fine sea island) in West Indies, 148
—— for paper, 155
—— in British India, improvement of, 37
—— Korea, 996
—— Manchuria, 868
—— Uganda, 668
—— industry of the Leeward Islands colony, 58
——, introduction of American, into Sind province, 135
——, Madras crop, 1914–15, 611
—— mills in China, 769
—— stalks, utilising, 580
—— waste in India, 868, 906
—— year book, 534
Cottons and woollens, continental, 318
——, foreign, 136
Council, 1914-15, 1; Hon. Richard Clere Parsons, M.A., elected a member, 261; annual report, 733; 1915-16, annual report, 747; elected, 750; Dugald Clerk, D.Sc., F.R.S., elected chairman, 789
Crace, J. D., *disc.*, testing pigments for permanence of colour, 92; *letter*, decorative textile industries and the designer's relation thereto, 320
Crane, failure of Panama Canal, 465
——, monster locomotive, 466
Cream-separator industry, Sweden, 427
Crewe, Most Hon. the Marquess of, K.G., P.C., *chair*, Indian trade and the war, 645
Crosthwaite, Sir Charles Haukes Todd, K.C.S.I., *obituary*, 683
Croysdale, T., *disc.*, Indian indigo industry, 126
Cuba, timber resources of, 350
Cundall, Frank, *letter*, the value of birds to man, 867

10th Meeting:—"Decorative textile industries, and the designer's relation thereto," by Arthur Wilcock, 271
11th Meeting:—"The economic position of Germany," by Professor W. J. Ashley, M.A., M.Com., Ph.D., 303
12th Meeting:—"Shakespeare's profession," by William Poel, 325
13th Meeting:—"Patent law reform," by John William Gordon, K.C., 356
14th Meeting:—"The uses of coal gas for industrial purposes," by H. M. Thornton, M.I.Mech.E., 401
15th Meeting:—"The work of the war refugees' committee," by Lady Lugard, 429
16th Meeting:—"The industrial uses of radium," by T. Thorne Baker, 490
17th Meeting:—"The state and the fisherman," by Moreton Frewen, 519
18th Meeting:—"The utilisation of solar energy," by A. S. E. Ackermann, B.Sc.(Eng.), A.M.Inst.C.E., 537
19th Meeting:—"On the measurement of the efficiency of domestic fires, and on a simple smokeless grate," by Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., 570
20th Meeting:—"Recent progress in pyrometry," by Chas. R. Darling, A.R.C.Sc.I., 589
SPECIAL LECTURE:—"Constantin Meunier et les sculpteurs Belges de son temps," by Paul Lambotte, 669; annual report, 741
SPECIAL WAR LECTURE:—*Notice*, 789; "Field telephones," by Charles Darling, A.R.C.Sc.I., 881
Meetings, hour of, 959
Memorial tablets, 115; first English theatre, 936
Mercantile marine of the world, 486
Mercerising in acid, 137
Messel, Dr. Rudolph, F.R.S., *disc.*, Britain and Germany in relation to the chemical trade, 56
Mestrovic, Ivan, works of, 816
Metals, munition, 799
Metalwork and jewellery, 96
———— (domestic) of the eighteenth century, *paper* by Wm. A. Young, 66
Meunier (Constantin) et les sculpteurs belges de son temps, *Special Lecture* by Paul Lambotte, 669
Mica in Canada, 667
——— India, 976
Milan and Lombardy, foreign population of, 463
Military academy at Quetta, 644
——— training in schools, 997
Milnes, Alfred, *disc.*, the economic position of Germany, 314
Mining cartridge, hydraulic, 20
Mitchell, A. H., *letter*, destruction of wasps, 891
Mitchell, P. Chalmers, M.A., D.Sc., F.R.S., presentation to, of medal for his paper on zoological gardens, 16
Moir, E. W., *letter*, munitions inventions department, 947
Molasses, new lubricant from, 772
———— problem in Cuba, 768

Molybdenum, Australian 587
——————, Canadian, 932
Moore, Lieut.-Colonel the Hon. Sir James Newton, K.C.M.G., *disc.*, the northern territory of Australia, 397
Moore, R. A. Leslie, *disc.*, Nepal, 245
Morris, Sir Daniel, K.C.M.G., D.C.L., D.Sc., *disc.*, the empire's resources in paper-making materials, 633
Morse, Samuel, and the Society of Arts, 448
Motor-cars and tyres (American) for England and France, 1001
———— in Norway, 503
———— fishing-boats in Scotland, 998
———— plough, 1032
